This is a program that is still being written. Many things are missing, including adequate documentation. This manual assumes that you already know how to program in Logo, and merely presents the details of this new implementation.

Read Computer Science Logo Style, Volume 1: Symbolic Computing by Brian Harvey (MIT Press, 1997) for a tutorial on Logo programming with emphasis on symbolic computation.

Here are the special features of this dialect of Logo:

Source file compatible among Unix, DOS, Windows, and Mac platforms.

Random-access arrays.

Variable number of inputs to user-defined procedures.

Mutators for list structure (dangerous).

Pause on error, and other improvements to error handling.

Comments and continuation lines; formatting is preserved when procedure definitions are saved or edited.

Terrapin-style tokenization (e.g., [2+3] is a list with one member) but LCSI-style syntax (no special forms except TO). The best of both worlds.

First-class instruction and expression templates (see APPLY).

Macros.
Features **not** found in Berkeley Logo include robotics, music, animation, parallelism, and multimedia. For those, buy a commercial version.

### 1.2 Getter/Setter Variable Syntax

Logo distinguishes *procedures* from *variables*. A procedure is a set of instructions to carry out some computation; a variable is a named container that holds a data value such as a number, word, list, or array.

In traditional Logo syntax, a non-numeric word typed without punctuation represents a request to invoke the procedure named by that word. A word typed with a preceding quotation mark represents the word itself. For example, in the instruction

```logo
PRINT FIRST "WORD
```

the procedures named `FIRST` and `PRINT` are invoked, but the procedure named `WORD` is not invoked; the word `W-O-R-D` is the input to `FIRST`.

What about variables? There are two things one can do with a variable: give it a value, and find out its value. To give a variable a value, Logo provides the primitive procedure `MAKE`, which requires two inputs: the name of the variable and the new value to be assigned. The first input, the name of the variable, is just a word, and if (as is almost always the case) the programmer wants to assign a value to a specific variable whose name is known in advance, that input is quoted, just as any known specific word would be:

```logo
MAKE "MY.VAR FIRST "WORD
```

gives the variable named `MY.VAR` the value `W` (the first letter of `WORD`).

To find the value of a variable, Logo provides the primitive procedure `THING`, which takes a variable name as its input, and outputs the value of the accessible variable with that name. Thus

```logo
PRINT THING "MY.VAR
```

will print `W` (supposing the `MAKE` above has been done). Since finding the value of a specific, known variable name is such a common operation, Logo also provides an abbreviated notation that combines `THING` with quote:

```logo
PRINT :MY.VAR
```

The colon (which Logo old-timers pronounce "dots") replaces `THING` and `"` in the earlier version of the instruction.

Newcomers to Logo often complain about the need for all this punctuation. In particular, Logo programmers who learned about dots and quotes without also learning about `THING` wonder why an instruction such as

```logo
MAKE "NEW.VAR :OLD.VAR
```

uses two different punctuation marks to identify the two variables. (Having read the paragraphs above, you will understand that actually both variable names are quoted, but the procedure `THING` is invoked to find the value of `OLD.VAR`, since it's that value, not `OLD.VAR`'s
name, that \texttt{MAKE} needs to know. It wouldn't make sense to ask for \texttt{THING} of \texttt{NEW.VAR}, since we haven't given \texttt{NEW.VAR} a value yet.)

Although Logo's punctuation rules make sense once understood, they do form a barrier to entry for the Logo beginner. Why, then, couldn't Logo be designed so that an unpunctuated word would represent a procedure if there is a procedure by that name, or a variable if there is a variable by that name? Then we could say

\begin{verbatim}
PRINT MY.VAR
\end{verbatim}

and Logo would realize that \texttt{MY.VAR} is the name of a variable, not of a procedure. The traditional reason not to use this convention is that Logo allows the same word to name a procedure and a variable at the same time. This is most often important for words that name data types, as in the following procedure:

\begin{verbatim}
TO PLURAL :WORD
  OUTPUT WORD :WORD "S
END
\end{verbatim}

Here the name \texttt{WORD} is a natural choice for the input to \texttt{PLURAL}, since it describes the kind of input that \texttt{PLURAL} expects. Within the procedure, we use \texttt{WORD} to represent Logo's primitive procedure that combines two input words to form a new, longer word; we use :\texttt{WORD} to represent the variable containing the input, whatever actual word is given when \texttt{PLURAL} is invoked.

\begin{verbatim}
? PRINT PLURAL "COMPUTER
COMPUTERS
\end{verbatim}

However, if a Logo instruction includes an unquoted word that is not the name of a procedure, Logo could look for a variable of that name instead. This would allow a "punctuationless" Logo, \textit{provided that users who want to work without colons for variables choose variable names that are not also procedure names.}

What about assigning a value to a variable? Could we do without the quotation mark on \texttt{MAKE}'s first input? Alas, no. Although the first input to \texttt{MAKE} is \textit{usually} a constant, known variable name, sometimes it isn't, as in this example:

\begin{verbatim}
TO INCREMENT :VAR
  MAKE :VAR (THING :VAR)+1 ; Note: it's not "VAR here!
END

? MAKE "X 5
? INCREMENT "X
? PRINT :X
6
\end{verbatim}

The procedure \texttt{INCREMENT} takes a variable name as its input and changes the value of that variable. In this example there are two variables; the variable whose name is \texttt{VAR}, and whose value is the word \texttt{X}; and the variable whose name is \texttt{X} and whose value changes from 5 to 6. Suppose we changed the behavior of \texttt{MAKE} so that it took the word after \texttt{MAKE} as the name of the variable to change; we would be unable to write \texttt{INCREMENT}:
TO INCREMENT :VAR ; nonworking!
MAKE VAR (THING VAR)+1
END

This would assign a new value to VAR, not to X.

What we can do is to allow an alternative to MAKE, a "setter" procedure for a particular variable. The notation will be

? SETFOO 7
? PRINT FOO
7

SETFOO is a "setter procedure" that takes one input (in this case the input 7) and assigns its value to the variable named FOO.

Berkeley Logo allows users to choose either the traditional notation, in which case the same name can be used both for a procedure and for a variable, or the getter/setter notation, in which variable FOO is set with SETFOO and examined with FOO, but the same name can’t be used for procedure and variable.

Here is how this choice is allowed: Berkeley Logo uses traditional notation, with procedures distinct from variables. However, if there is a variable named AllowGetSet whose value is TRUE (which there is, by default, when Logo starts up), then if a Logo instruction refers to a nonexistent procedure (so that the error message "I don’t know how to ..." would result), Logo tries the following two steps:

1. If the name is at least four characters long, and the first three characters are the letters SET (upper or lower case), and if the name is followed in the instruction by another value, and if the name without the SET is the name of a variable that already exists, then Logo will invoke MAKE with its first input being the name without the SET, and its second input being the following value.

2. If step 1’s conditions are not met, but the name is the name of an accessible variable, then Logo will invoke THING with that name as input, to find the variable’s value.

Step 1 requires that the variable already exist so that misspellings of names of SETxxx primitives (e.g., SETHEADING) will still be caught, instead of silently creating a new variable. The command GLOBAL can be used to create a variable without giving it a value.

One final point: The TO command in Logo has always been a special case; the rest of the line starting with TO is not evaluated as ordinary Logo expressions are. In particular, the colons used to mark the names of inputs to the procedure do not cause THING to be invoked. They are merely mnemonic aids, reminding the Logo user that these words are names of variables. (Arguably, this nonstandard behavior of TO adds to Logo beginners’ confusion about colons.) To a programmer using colonless variable references, the colons in the TO line are unnecessary and meaningless. Berkeley Logo therefore makes the colons optional:

TO FOO :IN1 :IN2
and

    TO FOO IN1 IN2

are both allowed.

1.3 Entering and Leaving Logo

The process to start Logo depends on your operating system:

Unix: Type the word logo to the shell. (The directory in which you’ve installed Logo must be in your path.)

DOS: Change directories to the one containing Logo (probably C:\UCBLOGO). Then type UCBLOGO for the large memory version, or BL for the 640K version.

Mac: Double-click on the LOGO icon within the "UCB Logo" folder.

Windows: Double-click on the UCBWLOGO icon in the UCBLOGO folder.

To leave Logo, enter the command bye.

On startup, Logo looks for a file named ‘startup.lg’ in the system Logo library and, if found, loads it. Then it looks for ‘startup.lg’ in the user’s home directory, or the current directory, depending on the operating system, and loads that. These startup files can be used to predefine procedures, e.g., to provide non-English names for primitive procedures.

Under Unix, DOS, or Windows, if you include one or more filenames on the command line when starting Logo, those files will be loaded before the interpreter starts reading commands from your terminal. If you load a file that executes some program that includes a bye command, Logo will run that program and exit. You can therefore write standalone programs in Logo and run them with shell/batch scripts. To support this technique, Logo does not print its usual welcoming and parting messages if you give file arguments to the logo command.

If a command line argument is just a hyphen, then all command line arguments after the hyphen are not taken as filenames, but are instead collected in a list, one word per argument; the buried variable COMMAND.LINE contains that list of arguments, or the empty list if there are none. On my Linux system, if the first line of an executable shell script is #!/usr/local/bin/logo - (note the hyphen) then the script can be given command line arguments and they all end up in :COMMAND.LINE along with the script’s path. Experiment.

If you type your interrupt character (see table below) Logo will stop what it’s doing and return to top-level, as if you did THROW "TOPLEVEL. If you type your quit character Logo will pause as if you did PAUSE.

<table>
<thead>
<tr>
<th></th>
<th>wxWidgets</th>
<th>Unix</th>
<th>DOS/Windows</th>
<th>Mac Classic</th>
</tr>
</thead>
<tbody>
<tr>
<td>toplevel</td>
<td>alt-S</td>
<td>usually ctrl-C</td>
<td>ctrl-Q</td>
<td>command-. (period)</td>
</tr>
<tr>
<td>pause</td>
<td>alt-P</td>
<td>usually ctrl-\</td>
<td>ctrl-W</td>
<td>command-, (comma)</td>
</tr>
</tbody>
</table>

If you have an environment variable called LOGOLIB whose value is the name of a directory, then Logo will use that directory instead of the default library. If you invoke a procedure
that has not been defined, Logo first looks for a file in the current directory named ‘\texttt{proc.lg}’ where \texttt{proc} is the procedure name in lower case letters. If such a file exists, Logo loads that file. If the missing procedure is still undefined, or if there is no such file, Logo then looks in the library directory for a file named ‘\texttt{proc}’ (no ‘.lg’) and, if it exists, loads it. If neither file contains a definition for the procedure, then Logo signals an error. Several procedures that are primitive in most versions of Logo are included in the default library, so if you use a different library you may want to include some or all of the default library in it.

\section*{1.4 Tokenization}

Names of procedures, variables, and property lists are case-insensitive. So are the special words \texttt{END}, \texttt{TRUE}, and \texttt{FALSE}. Case of letters is preserved in everything you type, however.

Within square brackets, words are delimited only by spaces and square brackets. \texttt{[2+3]} is a list containing one word. Note, however, that the Logo primitives that interpret such a list as a Logo instruction or expression (\texttt{RUN}, \texttt{IF}, etc.) reparse the list as if it had not been typed inside brackets.

After a quotation mark outside square brackets, a word is delimited by a space, a square bracket, or a parenthesis.

A word not after a quotation mark or inside square brackets is delimited by a space, a bracket, a parenthesis, or an infix operator $\texttt{+-*/=<>}$

A word consisting of a question mark followed by a number (e.g., \texttt{?37}), when runparsed (i.e., where a procedure name is expected), is treated as if it were the sequence

\begin{verbatim}
( ? 37 )
\end{verbatim}

making the number an input to the \texttt{?} procedure. (See the discussion of templates, below.) This special treatment does not apply to words read as data, to words with a non-number following the question mark, or if the question mark is backslashed.

A line (an instruction line or one read by \texttt{READLIST} or \texttt{READWORD}) can be continued onto the following line if its last character is a tilde (\texttt{~}). \texttt{READWORD} preserves the tilde and the newline; \texttt{READLIST} does not.

Lines read with \texttt{READRAWLINE} are never continued.

An instruction line or a line read by \texttt{READLIST} (but not by \texttt{READWORD}) is automatically continued to the next line, as if ended with a tilde, if there are unmatched brackets, parentheses, braces, or vertical bars pending. However, it’s an error if the continuation line contains only the word \texttt{END}; this is to prevent runaway procedure definitions. Lines explicitly continued with a tilde avoid this restriction.

If a line being typed interactively on the keyboard is continued, either with a tilde or automatically, Logo will display a tilde as a prompt character for the continuation line.
A semicolon begins a comment in an instruction line. Logo ignores characters from the semicolon to the end of the line. A tilde as the last character still indicates a continuation line, but not a continuation of the comment. For example, typing the instruction

```
print "abc;comment ~
def
```

will print the word abcdef. Semicolon has no special meaning in data lines read by READWORD or READLIST, but such a line can later be reparsed using RUNPARSE and then comments will be recognized.

The two-character sequence `#!` at the beginning of a line also starts a comment. Unix users can therefore write a file containing Logo commands, starting with the line

```
#! /usr/local/bin/logo
```

(or wherever your Logo executable lives) and the file will be executable directly from the shell.

To include an otherwise delimiting character (including semicolon or tilde) in a word, precede it with backslash (`\`). If the last character of a line is a backslash, then the newline character following the backslash will be part of the last word on the line, and the line continues onto the following line. To include a backslash in a word, use `\\`. If the combination backslash-newline is entered at the terminal, Logo will issue a backslash as a prompt character for the continuation line. All of this applies to data lines read with READWORD or READLIST as well as to instruction lines.

A line read with READRAWLINE has no special quoting mechanism; both backslash and vertical bar (described below) are just ordinary characters.

An alternative notation to include otherwise delimiting characters in words is to enclose a group of characters in vertical bars. All characters between vertical bars are treated as if they were letters. In data read with READWORD the vertical bars are preserved in the resulting word. In data read with READLIST (or resulting from a PARSE or RUNPARSE of a word) the vertical bars do not appear explicitly; all potentially delimiting characters (including spaces, brackets, parentheses, and infix operators) appear unmarked, but tokenized as though they were letters. Within vertical bars, backslash may still be used; the only characters that must be backslashed in this context are backslash and vertical bar themselves.

Characters entered between vertical bars are forever special, even if the word or list containing them is later reparsed with PARSE or RUNPARSE. Characters typed after a backslash are treated somewhat differently: When a quoted word containing a backslashed character is runparsed, the backslashed character loses its special quality and acts thereafter as if typed normally. This distinction is important only if you are building a Logo expression out of parts, to be RUN later, and want to use parentheses. For example,

```
PRINT RUN (SE "\( 2 " + 3 "\))
```

will print 5, but

```
RUN (SE "MAKE "||(1 2))
```
will create a variable whose name is open-parenthesis. (Each example would fail if vertical bars and backslashes were interchanged.)

A normally delimiting character entered within vertical bars is \texttt{EQUALP} to the same character without the vertical bars, but can be distinguished by the \texttt{VBARREDP} predicate. (However, \texttt{VBARREDP} returns \texttt{TRUE} only for characters for which special treatment is necessary: white-space, parentheses, brackets, infix operators, backslash, vertical bar, tilde, quote, question mark, colon, and semicolon.)
2 Data Structure Primitives

2.1 Constructors

word

    WORD word1 word2
    (WORD word1 word2 word3 ...)

outputs a word formed by concatenating its inputs.

list

    LIST thing1 thing2
    (LIST thing1 thing2 thing3 ...)

outputs a list whose members are its inputs, which can be any Logo datum (word, list, or array).

sentence

    SENTENCE thing1 thing2
    SE thing1 thing2
    (SENTENCE thing1 thing2 thing3 ...)
    (SE thing1 thing2 thing3 ...)

outputs a list whose members are its inputs, if those inputs are not lists, or the members of its inputs, if those inputs are lists.

fput

    FPUT thing list

outputs a list equal to its second input with one extra member, the first input, at the beginning. If the second input is a word, then the first input must be a one-letter word, and FPUT is equivalent to WORD.

lput

    LPUT thing list

outputs a list equal to its second input with one extra member, the first input, at the end. If the second input is a word, then the first input must be a one-letter word, and LPUT is equivalent to WORD with its inputs in the other order.

array

    ARRAY size
    (ARRAY size origin)

outputs an array of size members (must be a positive integer), each of which initially is an empty list. Array members can be selected with ITEM and changed with SETITEM. The first member of the array is member number 1 unless an origin input (must be an integer) is given, in which case the first member of the array has that number as its index. (Typically
0 is used as the origin if anything.) Arrays are printed by PRINT and friends, and can be typed in, inside curly braces; indicate an origin with \{a b c\}@0.

See [ITEM], page 12, [SETITEM], page 12, [PRINT], page 19.

**mdarray**

\[
\text{MDARRAY sizelist (library procedure)} \\
\quad (\text{MDARRAY sizelist origin})
\]

outputs a multi-dimensional array. The first input must be a list of one or more positive integers. The second input, if present, must be a single integer that applies to every dimension of the array.

Ex: (MDARRAY [3 5] 0) outputs a two-dimensional array whose members range from [0 0] to [2 4].

**listtoarray**

\[
\text{LISTTOARRAY list} \\
\quad (\text{LISTTOARRAY list origin})
\]

outputs an array of the same size as the input list, whose members are the members of the input list.

**arraytolist**

\[
\text{ARRAYTOLIST array}
\]

outputs a list whose members are the members of the input array. The first member of the output is the first member of the array, regardless of the array’s origin.

**combine**

\[
\text{COMBINE thing1 thing2 (library procedure)} \\
\quad \text{if thing2 is a word, outputs \text{WORD thing1 thing2}. If thing2 is a list, outputs \text{FPUT thing1 thing2}.}
\]

See [WORD], page 9, [FPUT], page 9

**reverse**

\[
\text{REVERSE list (library procedure)}
\]

outputs a list whose members are the members of the input list, in reverse order.

**gensym**

\[
\text{GENSYM (library procedure)}
\]

outputs a unique word each time it’s invoked. The words are of the form G1, G2, etc.

### 2.2 Data Selectors

**first**

\[
\text{FIRST thing}
\]
if the input is a word, outputs the first character of the word. If the input is a list, outputs
the first member of the list. If the input is an array, outputs the origin of the array (that
is, the index of the first member of the array).

**firsts**

FIRSTS list

outputs a list containing the FIRST of each member of the input list. It is an error if any
member of the input list is empty. (The input itself may be empty, in which case the output
is also empty.) This could be written as

```plaintext
to firsts :list
  output map "first :list
end
```

but is provided as a primitive in order to speed up the iteration tools MAP, MAP.SE, and
FOREACH.

```plaintext
to transpose :matrix
  if emptyp first :matrix [op [[]]
    op fput firsts :matrix transpose bfs :matrix
  end
See [MAP], page 77, [MAPdSE], page 77, [FOREACH], page 76
```

**last**

LAST wordorlist

if the input is a word, outputs the last character of the word. If the input is a list, outputs
the last member of the list.

**butfirst**

BUTFIRST wordorlist
BF wordorlist

if the input is a word, outputs a word containing all but the first character of the input. If
the input is a list, outputs a list containing all but the first member of the input.

**butfirsts**

BUTFIRSTS list
BFS list

outputs a list containing the BUTFIRST of each member of the input list. It is an error if any
member of the input list is empty or an array. (The input itself may be empty, in which
case the output is also empty.) This could be written as

```plaintext
to butfirsts :list
  output map "butfirst :list
end
```
but is provided as a primitive in order to speed up the iteration tools \texttt{MAP}, \texttt{MAP.SE}, and \texttt{FOREACH}.

See [MAP], page 77, [MAPdSE], page 77, [FOREACH], page 76

\textbf{butlast}

\begin{verbatim}
  BUTLAST wordorlist
  BL wordorlist
\end{verbatim}

if the input is a word, outputs a word containing all but the last character of the input. If the input is a list, outputs a list containing all but the last member of the input.

\textbf{item}

\begin{verbatim}
  ITEM index thing
\end{verbatim}

if the \textit{thing} is a word, outputs the \textit{index}th character of the word. If the \textit{thing} is a list, outputs the \textit{index}th member of the list. If the \textit{thing} is an array, outputs the \textit{index}th member of the array. Index starts at 1 for words and lists; the starting index of an array is specified when the array is created.

\textbf{mditem}

\begin{verbatim}
  MDITEM indexlist array (library procedure)
\end{verbatim}

outputs the member of the multidimensional \textit{array} selected by the list of numbers \textit{indexlist}.

\textbf{pick}

\begin{verbatim}
  PICK list (library procedure)
\end{verbatim}

outputs a randomly chosen member of the input list.

\textbf{remove}

\begin{verbatim}
  REMOVE thing list (library procedure)
\end{verbatim}

outputs a copy of \textit{list} with every member equal to \textit{thing} removed.

\textbf{remdup}

\begin{verbatim}
  REMDUP list (library procedure)
\end{verbatim}

outputs a copy of \textit{list} with duplicate members removed. If two or more members of the input are equal, the rightmost of those members is the one that remains in the output.

\textbf{quoted}

\begin{verbatim}
  QUOTED thing (library procedure)
\end{verbatim}

outputs its input, if a list; outputs its input with a quotation mark prepended, if a word.

\section*{2.3 Data Mutators}

\textbf{setitem}

\begin{verbatim}
  SETITEM index array value
\end{verbatim}
command. Replaces the indexth member of array with the new value. Ensures that the resulting array is not circular, i.e., value may not be a list or array that contains array.

**mdsetitem**

**MDSETITEM** indexlist array value (library procedure)

command. Replaces the member of array chosen by indexlist with the new value.

**.setfirst**

**.SETFIRST** list value

command. Changes the first member of list to be value.

WARNING: Primitives whose names start with a period are dangerous. Their use by non-experts is not recommended. The use of **.SETFIRST** can lead to circular list structures, which will get some Logo primitives into infinite loops, and to unexpected changes to other data structures that share storage with the list being modified.

**.setbf**

**.SETBF** list value

command. Changes the butfirst of list to be value.

WARNING: Primitives whose names start with a period are dangerous. Their use by non-experts is not recommended. The use of **.SETBF** can lead to circular list structures, which will get some Logo primitives into infinite loops; unexpected changes to other data structures that share storage with the list being modified; or to Logo crashes and coredumps if the butfirst of a list is not itself a list.

**.setitem**

**.SETITEM** index array value

command. Changes the indexth member of array to be value, like **SETITEM**, but without checking for circularity.

WARNING: Primitives whose names start with a period are dangerous. Their use by non-experts is not recommended. The use of **.SETITEM** can lead to circular arrays, which will get some Logo primitives into infinite loops.

See [**SETITEM**], page 12.

**push**

**PUSH** stackname thing (library procedure)

command. Adds the thing to the stack that is the value of the variable whose name is stackname. This variable must have a list as its value; the initial value should be the empty list. New members are added at the front of the list.

**pop**

**POP** stackname (library procedure)
outputs the most recently PUSHed member of the stack that is the value of the variable whose name is *stackname* and removes that member from the stack.

**queue**

QUEUE queuename thing (library procedure)

command. Adds the *thing* to the queue that is the value of the variable whose name is *queuename*. This variable must have a list as its value; the initial value should be the empty list. New members are added at the back of the list.

**dequeue**

DEQUEUE queuename (library procedure)

outputs the least recently QUEUED member of the queue that is the value of the variable whose name is *queuename* and removes that member from the queue.

### 2.4 Predicates

**wordp**

WORDP thing
WORD? thing

outputs TRUE if the input is a word, FALSE otherwise.

**listp**

LISTP thing
LIST? thing

outputs TRUE if the input is a list, FALSE otherwise.

**arrayp**

ARRAYP thing
ARRAY? thing

outputs TRUE if the input is an array, FALSE otherwise.

**emptyp**

EMPTYP thing
EMPTY? thing

outputs TRUE if the input is the empty word or the empty list, FALSE otherwise.

**equalp**

EQUALP thing1 thing2
EQUAL? thing1 thing2
thing1 = thing2

outputs TRUE if the inputs are equal, FALSE otherwise. Two numbers are equal if they have the same numeric value. Two non-numeric words are equal if they contain the same
characters in the same order. If there is a variable named \texttt{CASEIGNOREDP} whose value is \texttt{TRUE}, then an upper case letter is considered the same as the corresponding lower case letter. (This is the case by default.) Two lists are equal if their members are equal. An array is only equal to itself; two separately created arrays are never equal even if their members are equal. (It is important to be able to know if two expressions have the same array as their value because arrays are mutable; if, for example, two variables have the same array as their values then performing \texttt{SETITEM} on one of them will also change the other.)

See \cite{CASEIGNOREDP}, page 89, \cite{SETITEM}, page 12

\textbf{notequalp}

\begin{verbatim}
NOTEQUALP thing1 thing2
NOTEQUAL? thing1 thing2
thing1 <> thing2
\end{verbatim}

outputs \texttt{FALSE} if the inputs are equal, \texttt{TRUE} otherwise. See \texttt{EQUALP} for the meaning of equality for different data types.

\textbf{beforep}

\begin{verbatim}
BEFOREP word1 word2
BEFORE? word1 word2
\end{verbatim}

outputs \texttt{TRUE} if \texttt{word1} comes before \texttt{word2} in ASCII collating sequence (for words of letters, in alphabetical order). Case-sensitivity is determined by the value of \texttt{CASEIGNOREDP}. Note that if the inputs are numbers, the result may not be the same as with \texttt{LESSP}; for example, \texttt{BEFOREP 3 12} is false because 3 collates after 1.

See \cite{CASEIGNOREDP}, page 89, \cite{LESSP}, page 32

\textbf{.eq}

\begin{verbatim}
.EQ thing1 thing2
\end{verbatim}

outputs \texttt{TRUE} if its two inputs are the same datum, so that applying a mutator to one will change the other as well. Outputs \texttt{FALSE} otherwise, even if the inputs are equal in value.

WARNING: Primitives whose names start with a period are \texttt{dangerous}. Their use by non-experts is not recommended. The use of mutators can lead to circular data structures, infinite loops, or Logo crashes.

\textbf{memberp}

\begin{verbatim}
MEMBERP thing1 thing2
MEMBER? thing1 thing2
\end{verbatim}

if \texttt{thing2} is a list or an array, outputs \texttt{TRUE} if \texttt{thing1} is \texttt{EQUALP} to a member of \texttt{thing2}, \texttt{FALSE} otherwise. If \texttt{thing2} is a word, outputs \texttt{TRUE} if \texttt{thing1} is a one-character word \texttt{EQUALP} to a character of \texttt{thing2}, \texttt{FALSE} otherwise.

See \cite{EQUALP}, page 14.
substringp

\texttt{SUBSTRINGP thing1 thing2 }
\texttt{SUBSTRING? thing1 thing2}

if \texttt{thing1} or \texttt{thing2} is a list or an array, outputs \texttt{FALSE}. If \texttt{thing2} is a word, outputs \texttt{TRUE} if \texttt{thing1} is \texttt{EQUALP} to a substring of \texttt{thing2}, \texttt{FALSE} otherwise.

See [EQUALP], page 14.

numberp

\texttt{NUMBERP thing }
\texttt{NUMBER? thing}

outputs \texttt{TRUE} if the input is a number, \texttt{FALSE} otherwise.

vbarredp

\texttt{VBARREDP char}
\texttt{VBARRED? char}
\texttt{BACKSLASHEDP char}
\texttt{BACKSLASHED? char (library procedure)}

outputs \texttt{TRUE} if the input character was originally entered into Logo within vertical bars (|) to prevent its usual special syntactic meaning, \texttt{FALSE} otherwise. (Outputs \texttt{TRUE} only if the character is a backslashed space, tab, newline, or one of \texttt{( }\texttt{|} \texttt{-} \texttt{)} \texttt{+} \texttt{/=<>}:;\~?| )

The names \texttt{BACKSLASHEDP} and \texttt{BACKSLASHED?} are included in the Logo library for backward compatibility with the former names of this primitive, although it does \texttt{not} output \texttt{TRUE} for characters originally entered with backslashes.

2.5 Queries

count

\texttt{COUNT thing}

outputs the number of characters in the input, if the input is a word; outputs the number of members in the input, if it is a list or an array. (For an array, this may or may not be the index of the last member, depending on the array’s origin.)

ascii

\texttt{ASCII char}

outputs the integer (between 0 and 255) that represents the input character in the ASCII code. Interprets control characters as representing vbarred punctuation, and returns the character code for the corresponding punctuation character without vertical bars. (Compare \texttt{RAWASCII}.)

rawascii

\texttt{RAWASCII char}
outputs the integer (between 0 and 255) that represents the input character in the ASCII code. Interprets control characters as representing themselves. To find out the ASCII code of an arbitrary keystroke, use \texttt{RAWASCII RC}.

\textbf{char}

\begin{verbatim}
CHAR int
\end{verbatim}

outputs the character represented in the ASCII code by the input, which must be an integer between 0 and 255.

See [ASCII], page 16.

\textbf{member}

\begin{verbatim}
MEMBER thing1 thing2
\end{verbatim}

if \texttt{thing2} is a word or list and if \texttt{MEMBERP} with these inputs would output \texttt{TRUE}, outputs the portion of \texttt{thing2} from the first instance of \texttt{thing1} to the end. If \texttt{MEMBERP} would output \texttt{FALSE}, outputs the empty word or list according to the type of \texttt{thing2}. It is an error for \texttt{thing2} to be an array.

See [MEMBERP], page 15.

\textbf{lowercase}

\begin{verbatim}
LOWERCASE word
\end{verbatim}

outputs a copy of the input word, but with all uppercase letters changed to the corresponding lowercase letter.

\textbf{uppercase}

\begin{verbatim}
UPPERCASE word
\end{verbatim}

outputs a copy of the input word, but with all lowercase letters changed to the corresponding uppercase letter.

\textbf{standout}

\begin{verbatim}
STANDOUT thing
\end{verbatim}

outputs a word that, when printed, will appear like the input but displayed in standout mode (boldface, reverse video, or whatever your version does for standout). The word contains machine-specific magic characters at the beginning and end; in between is the printed form (as if displayed using \texttt{TYPE}) of the input. The output is always a word, even if the input is of some other type, but it may include spaces and other formatting characters. Note: a word output by \texttt{STANDOUT} while Logo is running on one machine will probably not have the desired effect if printed on another type of machine.

In the Macintosh classic version, the way that standout works is incompatible with the use of characters whose ASCII code is greater than 127. Therefore, you have a choice to make: The instruction

\begin{verbatim}
CANINVERSE 0
\end{verbatim}
disables standout, but enables the display of ASCII codes above 127, and the instruction

\[ \text{CANINVERSE 1} \]

restores the default situation in which standout is enabled and the extra graphic characters cannot be printed.

**parse**

\[ \text{PARSE word} \]

outputs the list that would result if the input word were entered in response to a `READLIST` operation. That is, `PARSE READWORD` has the same value as `READLIST` for the same characters read.

See [READLIST], page 20 , [READWORD], page 20

**runparse**

\[ \text{RUNPARSE wordorlist} \]

outputs the list that would result if the input word or list were entered as an instruction line; characters such as infix operators and parentheses are separate members of the output. Note that sublists of a runparsed list are not themselves runparsed.
3 Communication

3.1 Transmitters

Note: If there is a variable named PRINTDEPTHLIMIT with a nonnegative integer value, then complex list and array structures will be printed only to the allowed depth. That is, members of members of... of members will be allowed only so far. The members omitted because they are just past the depth limit are indicated by an ellipsis for each one, so a too-deep list of two members will print as [ ... ... ].

If there is a variable named PRINTWIDTHLIMIT with a nonnegative integer value, then only the first so many members of any array or list will be printed. A single ellipsis replaces all missing data within the structure. The width limit also applies to the number of characters printed in a word, except that a PRINTWIDTHLIMIT between 0 and 9 will be treated as if it were 10 when applied to words. This limit applies not only to the top-level printed datum but to any substructures within it.

See [PRINTDEPTHLIMIT], page 90, [PRINTWIDTHLIMIT], page 90

If there is a variable named FULLPRINTP whose value is TRUE, then words that were created using backslash or vertical bar (to include characters that would otherwise not be treated as part of a word) are printed with the backslashes or vertical bars shown, so that the printed result could be re-read by Logo to produce the same value. If FULLPRINTP is TRUE then the empty word (however it was created) prints as ||. (Otherwise it prints as nothing at all.)

See [FULLPRINTP], page 90.

print

    PRINT thing
    PR thing
    (PRINT thing1 thing2 ...)
    (PR thing1 thing2 ...)

command. Prints the input or inputs to the current write stream (initially the screen). All the inputs are printed on a single line, separated by spaces, ending with a newline. If an input is a list, square brackets are not printed around it, but brackets are printed around sublists. Braces are always printed around arrays.

type

    TYPE thing
    (TYPE thing1 thing2 ...)

command. Prints the input or inputs like PRINT, except that no newline character is printed at the end and multiple inputs are not separated by spaces. Note: printing to the screen is ordinarily line buffered; that is, the characters you print using TYPE will not actually appear on the screen until either a newline character is printed (for example, by PRINT or SHOW) or Logo tries to read from the keyboard (either at the request of your program or after an instruction prompt). This buffering makes the program much faster than it would be if each character appeared immediately, and in most cases the effect is not disconcerting. To
accommodate programs that do a lot of positioned text display using TYPE. Logo will force printing whenever SETCURSOR is invoked. This solves most buffering problems. Still, on occasion you may find it necessary to force the buffered characters to be printed explicitly; this can be done using the WAIT command. WAIT 0 will force printing without actually waiting.

See [SETCURSOR], page 26, [WAIT], page 71

**show**

```
SHOW thing
(SHOW thing1 thing2 ...)
```

command. Prints the input or inputs like PRINT, except that if an input is a list it is printed inside square brackets.

See [PRINT], page 19.

### 3.2 Receivers

**readlist**

```
READLIST
RL
```
reads a line from the read stream (initially the keyboard) and outputs that line as a list. The line is separated into members as though it were typed in square brackets in an instruction. If the read stream is a file, and the end of file is reached, READLIST outputs the empty word (not the empty list). READLIST processes backslash, vertical bar, and tilde characters in the read stream; the output list will not contain these characters but they will have had their usual effect. READLIST does not, however, treat semicolon as a comment character.

**readword**

```
READWORD
RW
```
reads a line from the read stream and outputs that line as a word. The output is a single word even if the line contains spaces, brackets, etc. If the read stream is a file, and the end of file is reached, READWORD outputs the empty list (not the empty word). READWORD processes backslash, vertical bar, and tilde characters in the read stream. In the case of a tilde used for line continuation, the output word does include the tilde and the newline characters, so that the user program can tell exactly what the user entered. Vertical bars in the line are also preserved in the output. Backslash characters are not preserved in the output.

**readrawline**

```
READRAWLINE
```
reads a line from the read stream and outputs that line as a word. The output is a single word even if the line contains spaces, brackets, etc. If the read stream is a file, and the end of file is reached, READRAWLINE outputs the empty list (not the empty word). READRAWLINE
outputs the exact string of characters as they appear in the line, with no special meaning for backslash, vertical bar, tilde, or any other formatting characters.

See [READWORD], page 20.

**readchar**

```
READCHAR
RC
```

reads a single character from the read stream and outputs that character as a word. If the read stream is a file, and the end of file is reached, **READCHAR** outputs the empty list (not the empty word). If the read stream is the keyboard, echoing is turned off when **READCHAR** is invoked, and remains off until **READLIST** or **READWORD** is invoked or a Logo prompt is printed. Backslash, vertical bar, and tilde characters have no special meaning in this context.

See [READLIST], page 20.

**readchars**

```
READCHARS num
RCS num
```

reads `num` characters from the read stream and outputs those characters as a word. If the read stream is a file, and the end of file is reached, **READCHARS** outputs the empty list (not the empty word). If the read stream is the keyboard, echoing is turned off when **READCHARS** is invoked, and remains off until **READLIST** or **READWORD** is invoked or a Logo prompt is printed. Backslash, vertical bar, and tilde characters have no special meaning in this context.

See [READLIST], page 20, [READWORD], page 20.

**shell**

```
SHELL command
(SHELL command wordflag)
```

Under Unix, outputs the result of running `command` as a shell command. (The command is sent to `/bin/sh`, not `csh` or other alternatives.) If the command is a literal list in the instruction line, and if you want a backslash character sent to the shell, you must use `\` to get the backslash through Logo’s reader intact. The output is a list containing one member for each line generated by the shell command. Ordinarily each such line is represented by a list in the output, as though the line were read using **READLIST**. If a second input is given, regardless of the value of the input, each line is represented by a word in the output as though it were read with **READWORD**. Example:

```
to dayofweek
  output first first shell [date]
end
```

This is **first first** to extract the first word of the first (and only) line of the shell output. Under MacOS X, **SHELL** works as under Unix. **SHELL** is not available under Mac Classic.
Under DOS, SHELL is a command, not an operation; it sends its input to a DOS command processor but does not collect the result of the command.

Under Windows, the wxWidgets version of Logo behaves as under Unix (except that DOS-style commands are understood; use dir rather than ls). The non-wxWidgets version behaves like the DOS version.

3.3 File Access

**setprefix**

```
SETPREFIX string
```

command. Sets a prefix that will be used as the implicit beginning of filenames in OPENREAD, OPENWRITE, OPENAPPEND, OPENUPDATE, LOAD, and SAVE commands. Logo will put the appropriate separator character (slash for Unix, backslash for DOS/Windows, colon for MacOS Classic) between the prefix and the filename entered by the user. The input to SETPREFIX must be a word, unless it is the empty list, to indicate that there should be no prefix.

See [OPENREAD], page 22 , See [OPENWRITE], page 22 , See [OPENAPPEND], page 23 , See [OPENUPDATE], page 23 , See [LOAD], page 63 , See [SAVE], page 62 .

**prefix**

```
PREFIX
```

outputs the current file prefix, or [] if there is no prefix.

See [SETPREFIX], page 22 .

**openread**

```
OPENREAD filename
```

command. Opens the named file for reading. The read position is initially at the beginning of the file.

**openwrite**

```
OPENWRITE filename
```

command. Opens the named file for writing. If the file already existed, the old version is deleted and a new, empty file created.

**OPENWRITE**, but not the other **OPEN** variants, will accept as input a two-element list, in which the first element must be a variable name, and the second must be a positive integer. A character buffer of the specified size will be created. When a **SETWRITE** is done with this same list (in the sense of .EQ, not a copy, so you must do something like

```lisp
? make "buf [foo 100]
? openwrite :buf
? setwrite :buf
   [...]  
? close :buf
```
and not just

? openwrite [foo 100]
? setwrite [foo 100]

and so on), the printed characters are stored in the buffer; when a CLOSE is done with the same list as input, the characters from the buffer (treated as one long word, even if spaces and newlines are included) become the value of the specified variable.

**openappend**

OPENAPPEND filename

command. Opens the named file for writing. If the file already exists, the write position is initially set to the end of the old file, so that newly written data will be appended to it.

**openupdate**

OPENUPDATE filename

command. Opens the named file for reading and writing. The read and write position is initially set to the end of the old file, if any. Note: each open file has only one position, for both reading and writing. If a file opened for update is both READER and WRITER at the same time, then SETREADPOS will also affect WRITEPOS and vice versa. Also, if you alternate reading and writing the same file, you must SETREADPOS between a write and a read, and SETWRITEPOS between a read and a write.

See [READER], page 25, [WRITER], page 25, [SETREADPOS], page 25, [SETWRITEPOS], page 25

**close**

CLOSE filename

command. Closes the named file. If the file was currently the reader or writer, then the reader or writer is changed to the keyboard or screen, as if SETREAD [] or SETWRITE [] had been done.

**allopen**

ALLOPEN

outputs a list whose members are the names of all files currently open. This list does not include the dribble file, if any.

**closeall**

CLOSEALL (library procedure)

command. Closes all open files. Abbreviates FOREACH ALLOPEN [CLOSE ?]

See [FOREACH], page 76, [CLOSE], page 23

**erasefile**

ERASEFILE filename
ERF filename
command. Erases (deletes, removes) the named file, which should not currently be open.

dribble
  DRIBBLE filename
command. Creates a new file whose name is the input, like OPENWRITE, and begins recording
in that file everything that is read from the keyboard or written to the terminal. That is,
this writing is in addition to the writing to WRITER. The intent is to create a transcript of
a Logo session, including things like prompt characters and interactions.
See [OPENWRITE], page 22, [WRITER], page 25

nodribble
  NODRIBBLE
command. Stops copying information into the dribble file, and closes the file.

setread
  SETREAD filename
command. Makes the named file the read stream, used for READLIST, etc. The file must
already be open with OPENREAD or OPENUPDATE. If the input is the empty list, then the read
stream becomes the keyboard, as usual. Changing the read stream does not close the file
that was previously the read stream, so it is possible to alternate between files.
See [READLIST], page 20, [OPENREAD], page 22, [OPENUPDATE], page 23

setwrite
  SETWRITE filename
command. Makes the named file the write stream, used for PRINT, etc. The file must
already be open with OPENWRITE, OPENAPPEND, or OPENUPDATE. If the input is the empty
list, then the write stream becomes the screen, as usual. Changing the write stream does
not close the file that was previously the write stream, so it is possible to alternate between
files.

If the input is a list, then its first element must be a variable name, and its second and last
element must be a positive integer; a buffer of that many characters will be allocated, and
will become the writestream. If the same list (same in the .EQ sense, not a copy) has been
used as input to OPENWRITE, then the already-allocated buffer will be used, and the writer
can be changed to and from this buffer, with all the characters accumulated as in a file.
When the same list is used as input to CLOSE, the contents of the buffer (as an unparsed
word, which may contain newline characters) will become the value of the named variable.
For compatibility with earlier versions, if the list has not been opened when the SETWRITE
is done, it will be opened implicitly, but the first SETWRITE after this one will implicitly
close it, setting the variable and freeing the allocated buffer.
See [PRINT], page 19, [OPENWRITE], page 22, [OPENAPPEND], page 23, [OPENUPDATE], page 23
reader
   READER
outputs the name of the current read stream file, or the empty list if the read stream is the terminal.

writer
   WRITER
outputs the name of the current write stream file, or the empty list if the write stream is the screen.

setreadpos
   SETREADPOS charpos
command. Sets the file pointer of the read stream file so that the next READLIST, etc., will begin reading at the charpos\textsuperscript{th} character in the file, counting from 0. (That is, SETREADPOS 0 will start reading from the beginning of the file.) Meaningless if the read stream is the keyboard.

See [READLIST], page 20 .

setwritepos
   SETWRITEPOS charpos
command. Sets the file pointer of the write stream file so that the next PRINT, etc., will begin writing at the charpos\textsuperscript{th} character in the file, counting from 0. (That is, SETWRITEPOS 0 will start writing from the beginning of the file.) Meaningless if the write stream is the screen.

See [PRINT], page 19 .

readpos
   READPOS
outputs the file position of the current read stream file.

writepos
   WRITEPOS
outputs the file position of the current write stream file.

eofp
   EOF? predicate, outputs TRUE if there are no more characters to be read in the read stream file, FALSE otherwise.
filep

FILEP filename
FILE? filename (library procedure)
predicate, outputs TRUE if a file of the specified name exists and can be read, FALSE otherwise.

3.4 Terminal Access

keyp

KEYP
KEY?
predicate, outputs TRUE if there are characters waiting to be read from the read stream. If the read stream is a file, this is equivalent to NOT EOFP. If the read stream is the terminal, then echoing is turned off and the terminal is set to cbreak (character at a time instead of line at a time) mode. It remains in this mode until some line-mode reading is requested (e.g., READLIST). The Unix operating system forgets about any pending characters when it switches modes, so the first KEYP invocation will always output FALSE.

See [EOFP], page 25, [READLIST], page 20

cleartext

CLEARTEXT
CT
command. Clears the text window.

setcursor

SETCURSOR vector
command. The input is a list of two numbers, the x and y coordinates of a text window position (origin in the upper left corner, positive direction is southeast). The text cursor is moved to the requested position. This command also forces the immediate printing of any buffered characters.

cursor

CURSOR
outputs a list containing the current x and y coordinates of the text cursor. Logo may get confused about the current cursor position if, e.g., you type in a long line that wraps around or your program prints escape codes that affect the screen strangely.

setmargins

SETMARGINS vector
command. The input must be a list of two numbers, as for SETCURSOR. The effect is to clear the screen and then arrange for all further printing to be shifted down and to the right according to the indicated margins. Specifically, every time a newline character is
printed (explicitly or implicitly) Logo will type \textit{x_margin} spaces, and on every invocation of \texttt{SETCURSOR} the margins will be added to the input \textit{x} and \textit{y} coordinates. (\texttt{CURSOR} will report the cursor position relative to the margins, so that this shift will be invisible to Logo programs.) The purpose of this command is to accommodate the display of terminal screens in lecture halls with inadequate TV monitors that miss the top and left edges of the screen.

See \texttt{[SETCURSOR]} on page 26.

\subsection*{SetTextColor}
\begin{verbatim}
  SETTEXTCOLOR foreground background
  SETTC foreground background
\end{verbatim}
command (wxWidgets only). The inputs are color numbers, or RGB color lists, as for turtle graphics. The foreground and background colors for the textscreen/splitscreen text window are changed to the given values. The change affects text already printed as well as future text printing; there is only one text color for the entire window.

Command (non-wxWidgets Windows and DOS extended only). The inputs are color numbers, as for turtle graphics. Future printing to the text window will use the specified colors for foreground (the characters printed) and background (the space under those characters). Using \texttt{STANDOUT} will revert to the default text window colors. In the DOS extended (\texttt{'ucblogo.exe'}) version, colors in textscreen mode are limited to numbers 0-7, and the coloring applies only to text printed by the program, not to the echoing of text typed by the user. Neither limitation applies to the text portion of splitscreen mode, which is actually drawn as graphics internally.

See \texttt{[STANDOUT]} on page 17.

\subsection*{IncreaseFont}
\begin{verbatim}
  INCREASEFONT
  DECREASEFONT
\end{verbatim}
command (wxWidgets only). Increase or decrease the size of the font used in the text and edit windows to the next larger or smaller available size.

\subsection*{SetTextSize}
\begin{verbatim}
  SETTEXTSIZE height
\end{verbatim}
command (wxWidgets only). Set the "point size" of the font used in the text and edit windows to the given integer input. The desired size may not be available, in which case the nearest available size will be used. Note: There is only a slight correlation between these integers and pixel sizes. Our rough estimate is that the number of pixels of height is about 1.5 times the point size, but it varies for different fonts. See \texttt{SETLABELHEIGHT} for a different approach used for the graphics window.

\subsection*{Textsize}
\begin{verbatim}
  TEXTSIZE
\end{verbatim}
(wxWidgets only) outputs the "point size" of the font used in the text and edit windows. See \texttt{SETTEXTSIZE} for a discussion of font sizing. See \texttt{LABELSIZE} for a different approach used for the graphics window.

\textbf{setfont}

\begin{verbatim}
SETFONT fontname
\end{verbatim}

command (wxWidgets only). Set the font family used in all windows to the one named by the input. Try \texttt{"Courier"} or \texttt{"Monospace"} as likely possibilities. Not all computers have the same fonts installed. It’s a good idea to stick with monospace fonts (ones in which all characters have the same width).

\textbf{font}

\begin{verbatim}
FONT
\end{verbatim}

(wxWidgets only) outputs the name of the font family used in all windows.
4 Arithmetic

4.1 Numeric Operations

sum

\[
\text{SUM} \ \text{num1} \ \text{num2} \\
\quad (\text{SUM} \ \text{num1} \ \text{num2} \ \text{num3} \ \ldots) \\
\quad \text{num1} + \ \text{num2}
\]

outputs the sum of its inputs.

difference

\[
\text{DIFFERENCE} \ \text{num1} \ \text{num2} \\
\quad \text{num1} - \ \text{num2}
\]

outputs the difference of its inputs. Minus sign means infix difference in ambiguous contexts (when preceded by a complete expression), unless it is preceded by a space and followed by a nonspace. (See also MINUS.)

minus

\[
\text{MINUS} \ \text{num} \\
\quad - \ \text{num}
\]

outputs the negative of its input. Minus sign means unary minus if the previous token is an infix operator or open parenthesis, or it is preceded by a space and followed by a nonspace. There is a difference in binding strength between the two forms:

\[
\text{MINUS} \ 3 + 4 \quad \text{means} \quad -(3+4) \\
\quad -3 + 4 \quad \text{means} \quad (-3)+4
\]

product

\[
\text{PRODUCT} \ \text{num1} \ \text{num2} \\
\quad (\text{PRODUCT} \ \text{num1} \ \text{num2} \ \text{num3} \ \ldots) \\
\quad \text{num1} * \ \text{num2}
\]

outputs the product of its inputs.

quotient

\[
\text{QUOTIENT} \ \text{num1} \ \text{num2} \\
\quad (\text{QUOTIENT} \ \text{num}) \\
\quad \text{num1} / \ \text{num2}
\]

outputs the quotient of its inputs. The quotient of two integers is an integer if and only if the dividend is a multiple of the divisor. (In other words, QUOTIENT 5 2 is 2.5, not 2, but QUOTIENT 4 2 is 2, not 2.0 — it does the right thing.) With a single input, QUOTIENT outputs the reciprocal of the input.
remainder
    REMAINDER num1 num2
outputs the remainder on dividing num1 by num2; both must be integers and the result is
an integer with the same sign as num1.

modulo
    MODULO num1 num2
outputs the remainder on dividing num1 by num2; both must be integers and the result is
an integer with the same sign as num2.

int
    INT num
outputs its input with fractional part removed, i.e., an integer with the same sign as the
input, whose absolute value is the largest integer less than or equal to the absolute value of
the input.

round
    ROUND num
outputs the nearest integer to the input.

sqrt
    SQRT num
outputs the square root of the input, which must be nonnegative.

power
    POWER num1 num2
outputs num1 to the num2 power. If num1 is negative, then num2 must be an integer.

exp
    EXP num
outputs $e \ (2.718281828+) \ to \ the \ input \ power.$

log10
    LOG10 num
outputs the common logarithm of the input.

ln
    LN num
outputs the natural logarithm of the input.

\textbf{sin}
\begin{itemize}
\item \textsc{SIN} degrees
\end{itemize}
outputs the sine of its input, which is taken in degrees.

\textbf{radsin}
\begin{itemize}
\item \textsc{RADSIN} radians
\end{itemize}
outputs the sine of its input, which is taken in radians.

\textbf{cos}
\begin{itemize}
\item \textsc{COS} degrees
\end{itemize}
outputs the cosine of its input, which is taken in degrees.

\textbf{radcos}
\begin{itemize}
\item \textsc{RADCOS} radians
\end{itemize}
outputs the cosine of its input, which is taken in radians.

\textbf{arctan}
\begin{itemize}
\item \textsc{ARCTAN} \textit{num}
\item (\textsc{ARCTAN} \textit{x y})
\end{itemize}
outputs the arctangent, in degrees, of its input. With two inputs, outputs the arctangent of y/x, if x is nonzero, or 90 or –90 depending on the sign of y, if x is zero.

\textbf{radarctan}
\begin{itemize}
\item \textsc{RADARCTAN} \textit{num}
\item (\textsc{RADARCTAN} \textit{x y})
\end{itemize}
outputs the arctangent, in radians, of its input. With two inputs, outputs the arctangent of y/x, if x is nonzero, or \(\pi/2\) or \(-\pi/2\) depending on the sign of y, if x is zero.

The expression \(2 \times (\textsc{RADARCTAN} \ 0 \ 1)\) can be used to get the value of \(\pi\).

\textbf{iseq}
\begin{itemize}
\item \textsc{ISEQ} \textit{from to} (library procedure)
\end{itemize}
outputs a list of the integers from \textit{from} to \textit{to}, inclusive.

\begin{verbatim}
  ? show iseq 3 7
[3 4 5 6 7]
  ? show iseq 7 3
[7 6 5 4 3]
\end{verbatim}

\textbf{rseq}
\begin{itemize}
\item \textsc{RSEQ} \textit{from to count} (library procedure)
\end{itemize}
outputs a list of \textit{count} equally spaced rational numbers between \textit{from} and \textit{to}, inclusive.
? show rseq 3 5 9
[3 3.25 3.5 3.75 4 4.25 4.5 4.75 5]
? show rseq 3 5
[3 3.5 4 4.5 5]

4.2 Numeric Predicates

lessp

LESSP num1 num2
LESS? num1 num2
num1 < num2

outputs TRUE if its first input is strictly less than its second.

greaterp

GREATERP num1 num2
GREATER? num1 num2
num1 > num2

outputs TRUE if its first input is strictly greater than its second.

lessequalp

LESSEQUALP num1 num2
LESSEQUAL? num1 num2
num1 <= num2

outputs TRUE if its first input is less than or equal to its second.

greaterequalp

GREATEREQUALP num1 num2
GREATEREQUAL? num1 num2
num1 >= num2

outputs TRUE if its first input is greater than or equal to its second.

4.3 Random Numbers

random

RANDOM num
(RANDOM start end)

with one input, outputs a random nonnegative integer less than its input, which must be a positive integer.

With two inputs, RANDOM outputs a random integer greater than or equal to the first input, and less than or equal to the second input. Both inputs must be integers, and the first must be less than the second. (RANDOM 0 9) is equivalent to RANDOM 10; (RANDOM 3 8) is equivalent to (RANDOM 6)+3.
rerandom

RERANDOM
(RERANDOM seed)

command. Makes the results of RANDOM reproducible. Ordinarily the sequence of random numbers is different each time Logo is used. If you need the same sequence of pseudo-random numbers repeatedly, e.g. to debug a program, say RERANDOM before the first invocation of RANDOM. If you need more than one repeatable sequence, you can give RERANDOM an integer input; each possible input selects a unique sequence of numbers.

4.4 Print Formatting

form

FORM num width precision

outputs a word containing a printable representation of num, possibly preceded by spaces (and therefore not a number for purposes of performing arithmetic operations), with at least width characters, including exactly precision digits after the decimal point. (If precision is 0 then there will be no decimal point in the output.)

As a debugging feature, (FORM num -1 format) will print the floating point num according to the C printf format, to allow

to hex :num
op form :num -1 "|%08X %08X|
end

to allow finding out the exact result of floating point operations. The precise format needed may be machine-dependent.

4.5 Bitwise Operations

bitand

BITAND num1 num2
(BITAND num1 num2 num3 ...)

outputs the bitwise and of its inputs, which must be integers.

See [AND], page 35.

bitor

BITOR num1 num2
(BITOR num1 num2 num3 ...)

outputs the bitwise or of its inputs, which must be integers.

See [OR], page 35.

bitxor

BITXOR num1 num2
(BITXOR num1 num2 num3 ...) outputs the bitwise exclusive or of its inputs, which must be integers.

See [OR], page 35.

**bitnot**

BITNOT num

outputs the bitwise *not* of its input, which must be an integer.

See [NOT], page 35.

**ashift**

ASHIFT num1 num2

outputs num1 arithmetic-shifted to the left by num2 bits. If num2 is negative, the shift is to the right with sign extension. The inputs must be integers.

**lshift**

LSHIFT num1 num2

outputs num1 logical-shifted to the left by num2 bits. If num2 is negative, the shift is to the right with zero fill. The inputs must be integers.
5 Logical Operations

and

\[
\text{AND } tf1 \text{ tf2} \\
(\text{AND } tf1 \text{ tf2} \text{ tf3} \ldots)
\]

outputs \text{TRUE} if all inputs are \text{TRUE}, otherwise \text{FALSE}. All inputs must be \text{TRUE} or \text{FALSE}. (Comparison is case-insensitive regardless of the value of \text{CASEIGNOREDP}. That is, \text{true} or \text{True} or \text{TRUE} are all the same.) An input can be a list, in which case it is taken as an expression to run; that expression must produce a \text{TRUE} or \text{FALSE} value. List expressions are evaluated from left to right; as soon as a \text{FALSE} value is found, the remaining inputs are not examined. Example:

\[
\text{MAKE "RESULT AND } [\text{NOT (:X = 0)}] [\{(1 / :X) > .5\}]
\]
to avoid the division by zero if the first part is false.

See [\text{CASEIGNOREDP}], page 89.

or

\[
\text{OR } tf1 \text{ tf2} \\
(\text{OR } tf1 \text{ tf2} \text{ tf3} \ldots)
\]

outputs \text{TRUE} if any input is \text{TRUE}, otherwise \text{FALSE}. All inputs must be \text{TRUE} or \text{FALSE}. (Comparison is case-insensitive regardless of the value of \text{CASEIGNOREDP}. That is, \text{true} or \text{True} or \text{TRUE} are all the same.) An input can be a list, in which case it is taken as an expression to run; that expression must produce a \text{TRUE} or \text{FALSE} value. List expressions are evaluated from left to right; as soon as a \text{TRUE} value is found, the remaining inputs are not examined. Example:

\[
\text{IF OR :X=0 [some.long.computation]} [...]
\]
to avoid the long computation if the first condition is met.

See [\text{CASEIGNOREDP}], page 89.

not

\[
\text{NOT } tf
\]

outputs \text{TRUE} if the input is \text{FALSE}, and vice versa. The input can be a list, in which case it is taken as an expression to run; that expression must produce a \text{TRUE} or \text{FALSE} value.
6 Graphics

Berkeley Logo provides traditional Logo turtle graphics with one turtle. Multiple turtles, dynamic turtles, and collision detection are not supported. This is the most hardware-dependent part of Logo; some features may exist on some machines but not others. Nevertheless, the goal has been to make Logo programs as portable as possible, rather than to take fullest advantage of the capabilities of each machine. In particular, Logo attempts to scale the screen so that turtle coordinates $[-100, -100]$ and $[100, 100]$ fit on the graphics window, and so that the aspect ratio is 1:1.

The center of the graphics window (which may or may not be the entire screen, depending on the machine used) is turtle location $[0, 0]$. Positive X is to the right; positive Y is up. Headings (angles) are measured in degrees clockwise from the positive Y axis. (This differs from the common mathematical convention of measuring angles counterclockwise from the positive X axis.) The turtle is represented as an isosceles triangle; the actual turtle position is at the midpoint of the base (the short side). However, the turtle is drawn one step behind its actual position, so that the display of the base of the turtle’s triangle does not obscure a line drawn perpendicular to it (as would happen after drawing a square).

Colors are, of course, hardware-dependent. However, Logo provides partial hardware independence by interpreting color numbers 0 through 7 uniformly on all computers:

<table>
<thead>
<tr>
<th>0</th>
<th>black</th>
<th>1</th>
<th>blue</th>
<th>2</th>
<th>green</th>
<th>3</th>
<th>cyan</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>red</td>
<td>5</td>
<td>magenta</td>
<td>6</td>
<td>yellow</td>
<td>7</td>
<td>white</td>
</tr>
</tbody>
</table>

Where possible, Logo provides additional user-settable colors; how many are available depends on the hardware and operating system environment. If at least 16 colors are available, Logo tries to provide uniform initial settings for the colors 8-15:

<table>
<thead>
<tr>
<th>8</th>
<th>brown</th>
<th>9</th>
<th>tan</th>
<th>10</th>
<th>forest</th>
<th>11</th>
<th>aqua</th>
</tr>
</thead>
<tbody>
<tr>
<td>12</td>
<td>salmon</td>
<td>13</td>
<td>purple</td>
<td>14</td>
<td>orange</td>
<td>15</td>
<td>grey</td>
</tr>
</tbody>
</table>

Logo begins with a black background and white pen.

6.1 Turtle Motion

forward

FORWARD dist
FD dist

moves the turtle forward, in the direction that it’s facing, by the specified distance (measured in turtle steps).

back

BACK dist
BK dist

moves the turtle backward, i.e., exactly opposite to the direction that it’s facing, by the specified distance. (The heading of the turtle does not change.)
left
    LEFT degrees
    LT degrees

turns the turtle counterclockwise by the specified angle, measured in degrees (1/360 of a circle).

right
    RIGHT degrees
    RT degrees

turns the turtle clockwise by the specified angle, measured in degrees (1/360 of a circle).

setpos
    SETPOS pos

moves the turtle to an absolute position in the graphics window. The input is a list of two numbers, the X and Y coordinates.

setxy
    SETXY xcor ycor

moves the turtle to an absolute position in the graphics window. The two inputs are numbers, the X and Y coordinates.

setx
    SETX xcor

moves the turtle horizontally from its old position to a new absolute horizontal coordinate. The input is the new X coordinate.

sety
    SETY ycor

moves the turtle vertically from its old position to a new absolute vertical coordinate. The input is the new Y coordinate.

setheading
    SETHEADING degrees
    SETH degrees

turns the turtle to a new absolute heading. The input is a number, the heading in degrees clockwise from the positive Y axis.

home
    HOME

moves the turtle to the center of the screen. Equivalent to SETPOS [0 0] SETHEADING 0. See [SETPOS], page 38, See [SETHEADING], page 38.
arc
    ARC angle radius
draws an arc of a circle, with the turtle at the center, with the specified radius, starting at
the turtle’s heading and extending clockwise through the specified angle. The turtle does
not move.

6.2 Turtle Motion Queries

pos
    POS
outputs the turtle’s current position, as a list of two numbers, the X and Y coordinates.

xcor
    XCOR (library procedure)
outputs a number, the turtle’s X coordinate.

ycor
    YCOR (library procedure)
outputs a number, the turtle’s Y coordinate.

heading
    HEADING
outputs a number, the turtle’s heading in degrees.

towards
    TOWARDS pos
outputs a number, the heading at which the turtle should be facing so that it would point
from its current position to the position given as the input.

scrunch
    SCRUNCH
outputs a list containing two numbers, the X and Y scrunch factors, as used by SETSCRUNCH.
(But note that SETSCRUNCH takes two numbers as inputs, not one list of numbers.)

See [SETSCRUNCH], page 42.

6.3 Turtle and Window Control

showturtle
    SHOWTURTLE
    ST
makes the turtle visible.
hideturtle

    HIDETURTLE
    HT

makes the turtle invisible. It's a good idea to do this while you're in the middle of a complicated drawing, because hiding the turtle speeds up the drawing substantially.

clean

    CLEAN

erases all lines that the turtle has drawn on the graphics window. The turtle's state (position, heading, pen mode, etc.) is not changed.

clearscreen

    CLEARSCREEN
    CS

erases the graphics window and sends the turtle to its initial position and heading. Like HOME and CLEAN together.

See [HOME], page 38.

wrap

    WRAP

tells the turtle to enter wrap mode: From now on, if the turtle is asked to move past the boundary of the graphics window, it will "wrap around" and reappear at the opposite edge of the window. The top edge wraps to the bottom edge, while the left edge wraps to the right edge. (So the window is topologically equivalent to a torus.) This is the turtle's initial mode. Compare WINDOW and FENCE.

See [FENCE], page 40.

window

    WINDOW

tells the turtle to enter window mode: From now on, if the turtle is asked to move past the boundary of the graphics window, it will move offscreen. The visible graphics window is considered as just part of an infinite graphics plane; the turtle can be anywhere on the plane. (If you lose the turtle, HOME will bring it back to the center of the window.) Compare WRAP and FENCE.

See [HOME], page 38.

fence

    FENCE

tells the turtle to enter fence mode: From now on, if the turtle is asked to move past the boundary of the graphics window, it will move as far as it can and then stop at the edge with an "out of bounds" error message. Compare WRAP and WINDOW.
fill
FILL
fills in a region of the graphics window containing the turtle and bounded by lines that have been drawn earlier. This is not portable; it doesn’t work for all machines, and may not work exactly the same way on different machines.

filled
FILLED color instructions
runs the instructions, remembering all points visited by turtle motion commands, starting and ending with the turtle’s initial position. Then draws (ignoring penmode) the resulting polygon, in the current pen color, filling the polygon with the given color, which can be a color number or an RGB list. The instruction list cannot include another FILLED invocation. (wxWidgets only)

label
LABEL text
takes a word or list as input, and prints the input on the graphics window, starting at the turtle’s position.

setlabelheight
SETLABELHEIGHT height
command (wxWidgets only). Takes a positive integer argument and tries to set the font size so that the character height (including descenders) is that many turtle steps. This will be different from the number of screen pixels if SETSCRUNCH has been used. Also, note that SETSCRUNCH changes the font size to try to preserve this height in turtle steps. Note that the query operation corresponding to this command is LABELSIZE, not LABELHEIGHT, because it tells you the width as well as the height of characters in the current font.

textscreen
TEXTSCREEN
TS
rearranges the size and position of windows to maximize the space available in the text window (the window used for interaction with Logo). The details differ among machines. Compare SPLITSCREEN and FULLSCREEN.

See [SPLITSCREEN], page 42.

fullscreen
FULLSCREEN
FS
rearranges the size and position of windows to maximize the space available in the graphics window. The details differ among machines. Compare SPLITSCREEN and TEXTSCREEN.
Since there must be a text window to allow printing (including the printing of the Logo prompt), Logo automatically switches from fullscreen to splitscreen whenever anything is printed.

In the DOS version, switching from fullscreen to splitscreen loses the part of the picture that’s hidden by the text window. [This design decision follows from the scarcity of memory, so that the extra memory to remember an invisible part of a drawing seems too expensive.]

`splitscreen`

```
splitscreen
ss
```

rearranges the size and position of windows to allow some room for text interaction while also keeping most of the graphics window visible. The details differ among machines. Compare `TEXTSCREEN` and `FULLSCREEN`.

See [TEXTSCREEN], page 41.

`setscrunch`

```
setscrunch xscale yscale
```

adjusts the aspect ratio and scaling of the graphics display. After this command is used, all further turtle motion will be adjusted by multiplying the horizontal and vertical extent of the motion by the two numbers given as inputs. For example, after the instruction `setscrunch 2 1` motion at a heading of 45 degrees will move twice as far horizontally as vertically. If your squares don’t come out square, try this. (Alternatively, you can deliberately misadjust the aspect ratio to draw an ellipse.)

For all modern computers, both scale factors are initially 1. For DOS machines, the scale factors are initially set according to what the hardware claims the aspect ratio is, but the hardware sometimes lies. For DOS, the values set by `setscrunch` are remembered in a file (called ‘scrunch.dat’) and are automatically put into effect when a Logo session begins.

`refresh`

```
refresh
```

(command) tells Logo to remember the turtle’s motions so that they can be used for high-resolution printing (wxWidgets) or to refresh the graphics window if it is moved, resized, or overlayed (non-wxWidgets). This is the default.

`noreferrer`

```
noreferrer
```

(command) tells Logo not to remember the turtle’s motions, which may be useful to save time and memory if your program is interactive or animated, rather than drawing a static picture you’ll want to print later (wxWidgets). In non-wxWidgets versions, using NOREFRESH may prevent Logo from restoring the graphics image after the window is moved, resized, or overlayed.

6.4 Turtle and Window Queries
shownp
  SHOWNP
  SHOWN?
outputs TRUE if the turtle is shown (visible), FALSE if the turtle is hidden. See SHOWTURTLE and HIDETURTLE.

See [SHOWTURTLE], page 39, [HIDETURTLE], page 40.

screenmode
  SCREENMODE
outputs the word TEXTSCREEN, SPLITSCREEN, or FULLSCREEN depending on the current screen mode.

turtlemode
  TURTLEMODE
outputs the word WRAP, FENCE, or WINDOW depending on the current turtle mode.

labels
  LABELSIZE
(outputs a list of two positive integers, the width and height of characters displayed by LABEL measured in turtle steps (which will be different from screen pixels if SETSCRUNCH has been used). There is no SETLABELSIZE because the width and height of a font are not separately controllable, so the inverse of this operation is SETLABELHEIGHT, which takes just one number for the desired height.

6.5 Pen and Background Control

The turtle carries a pen that can draw pictures. At any time the pen can be UP (in which case moving the turtle does not change what’s on the graphics screen) or DOWN (in which case the turtle leaves a trace). If the pen is down, it can operate in one of three modes: PAINT (so that it draws lines when the turtle moves), ERASE (so that it erases any lines that might have been drawn on or through that path earlier), or REVERSE (so that it inverts the status of each point along the turtle’s path).

pendown
  PENDOWN
  PD
sets the pen’s position to DOWN, without changing its mode.

penup
  PENUP
  PU
sets the pen’s position to UP, without changing its mode.
penpaint
  PENPAINT
  PPT
sets the pen’s position to DOWN and mode to PAINT.

penerase
  PENERASE
  PE
sets the pen’s position to DOWN and mode to ERASE.
See [ERASE], page 57.

penreverse
  PENREVERSE
  PX
sets the pen’s position to DOWN and mode to REVERSE. (This may interact in system-dependent ways with use of color.)
See [REVERSE], page 10.

setpencolor
  SETPENCOLOR colornumber.or.rgblist
  SETPC colornumber.or.rgblist
sets the pen color to the given number, which must be a nonnegative integer. There are initial assignments for the first 16 colors:

  0 black 1 blue 2 green 3 cyan
  4 red 5 magenta 6 yellow 7 white
  8 brown 9 tan 10 forest 11 aqua
  12 salmon 13 purple 14 orange 15 grey

but other colors can be assigned to numbers by the PALETTE command. Alternatively, sets the pen color to the given RGB values (a list of three nonnegative numbers less than 100 specifying the percent saturation of red, green, and blue in the desired color).

setpalette
  SETPALETTE colornumber rgblist
sets the actual color corresponding to a given number, if allowed by the hardware and operating system. Colornumber must be an integer greater than or equal to 8. (Logo tries to keep the first 8 colors constant.) The second input is a list of three nonnegative numbers less than 100 specifying the percent saturation of red, green, and blue in the desired color.

setpensize
  SETPENSIZE size
sets the thickness of the pen. The input is either a single positive integer or a list of two positive integers (for horizontal and vertical thickness). Some versions pay no attention to the second number, but always have a square pen.

**setpenpattern**

`SETPENPATTERN pattern`

sets hardware-dependent pen characteristics. This command is not guaranteed compatible between implementations on different machines.

**setpen**

`SETPEN list` (library procedure)

sets the pen’s position, mode, thickness, and hardware-dependent characteristics according to the information in the input list, which should be taken from an earlier invocation of `PEN`.

See [PEN], page 46.

**setbackground**

`SETBACKGROUND colormnumber.or.rgblist`

`SETBG colormnumber.or.rgblist`

set the screen background color by slot number or RGB values. See `SETPENCOLOR` for details.

See [SETPENCOLOR], page 44.

### 6.6 Pen Queries

**pendownp**

`PENDOWNP`

`PENDOWN?`

outputs TRUE if the pen is down, FALSE if it’s up.

**penmode**

`PENMODE`

outputs one of the words `PAINT`, `ERASE`, or `REVERSE` according to the current pen mode.

See [ERASE], page 57, [REVERSE], page 10.

**pencolor**

`PENCOLOR`

`PC`

outputs a color number, a nonnegative integer that is associated with a particular color, or a list of RGB values if such a list was used as the most recent input to `SETPENCOLOR`. There are initial assignments for the first 16 colors:

0 black 1 blue 2 green 3 cyan
but other colors can be assigned to numbers by the PALETTE command.

**palette**

```logo
PALETTE colornumber
```

outputs a list of three nonnegative numbers less than 100 specifying the percent saturation of red, green, and blue in the color associated with the given number.

**pensize**

```logo
PENSIZE
```

outputs a list of two positive integers, specifying the horizontal and vertical thickness of the turtle pen. (In some implementations, including wxWidgets, the two numbers are always equal.)

```logo
PENPATTERN
```

outputs system-specific pen information.

**pen**

```logo
PEN (library procedure)
```

outputs a list containing the pen’s position, mode, thickness, and hardware-specific characteristics, for use by SETPEN.

See [SETPEN], page 45.

**background**

```logo
BACKGROUND
BG
```

outputs the graphics background color, either as a slot number or as an RGB list, whichever way it was set. (See PENCOLOR.)

### 6.7 Saving and Loading Pictures

**savepict**

```logo
SAVEPICT filename
```

command. Writes a file with the specified name containing the state of the graphics window, including any nonstandard color palette settings, in Logo’s internal format. This picture can be restored to the screen using LOADPICT. The format is not portable between platforms, nor is it readable by other programs. [EPSPICT], page 47 to export Logo graphics for other programs.

**loadpict**

```logo
LOADPICT filename
```
command. Reads the specified file, which must have been written by a \texttt{SAVEPICT} command, and restores the graphics window and color palette settings to the values stored in the file. Any drawing previously on the screen is cleared.

See \cite{SAVEPICT}, page 46.

\textbf{epspict}

\texttt{EPSPICT} \texttt{filename}

command. Writes a file with the specified name, containing an Encapsulated Postscript (EPS) representation of the state of the graphics window. This file can be imported into other programs that understand EPS format. Restrictions: the drawing cannot use \texttt{FILL}, \texttt{PENERASE}, or \texttt{PENREVERSE}; any such instructions will be ignored in the translation to Postscript form.

See \cite{FILL}, page 41, See \cite{PENERASE}, page 44, See \cite{PENREVERSE}, page 44.

\section*{6.8 Mouse Queries}

\textbf{mousepos}

\texttt{MOUSEPOS}

outputs the coordinates of the mouse, provided that it’s within the graphics window, in turtle coordinates. If the mouse is outside the graphics window, then the last position within the window is returned. Exception: If a mouse button is pressed within the graphics window and held while the mouse is dragged outside the window, the mouse’s position is returned as if the window were big enough to include it.

\textbf{clickpos}

\texttt{CLICKPOS}

outputs the coordinates that the mouse was at when a mouse button was most recently pushed, provided that that position was within the graphics window, in turtle coordinates. (wxWidgets only)

\textbf{buttonp}

\texttt{BUTTONP} \texttt{BUTTON?}

outputs \texttt{TRUE} if a mouse button is down and the mouse is over the graphics window. Once the button is down, \texttt{BUTTONP} remains true until the button is released, even if the mouse is dragged out of the graphics window.

\textbf{button}

\texttt{BUTTON}

outputs 0 if no mouse button has been pushed inside the Logo window since the last call to \texttt{BUTTON}. Otherwise, it outputs an integer between 1 and 3 indicating which button was most recently pressed. Ordinarily 1 means left, 2 means right, and 3 means center, but operating systems may reconfigure these.
7 Workspace Management

7.1 Procedure Definition

to

TO procname :input1 :input2 ... (special form)

command. Prepares Logo to accept a procedure definition. The procedure will be named procname and there must not already be a procedure by that name. The inputs will be called input1 etc. Any number of inputs are allowed, including none. Names of procedures and inputs are case-insensitive.

Unlike every other Logo procedure, TO takes as its inputs the actual words typed in the instruction line, as if they were all quoted, rather than the results of evaluating expressions to provide the inputs. (That’s what special form means.)

This version of Logo allows variable numbers of inputs to a procedure. After the procedure name come four kinds of things, in this order:

1. 0 or more REQUIRED inputs :FOO :FROBOZZ
2. 0 or more OPTIONAL inputs [:BAZ 87] [:THINGO 5+9]
3. 0 or 1 REST input [:GARPLY]
4. 0 or 1 DEFAULT number 5

Every procedure has a minimum, default, and maximum number of inputs. (The latter can be infinite.)

The minimum number of inputs is the number of required inputs, which must come first. A required input is indicated by the

:inputname

notation.

After all the required inputs can be zero or more optional inputs, each of which is represented by the following notation:

[:inputname default.value.expression]

When the procedure is invoked, if actual inputs are not supplied for these optional inputs, the default value expressions are evaluated to set values for the corresponding input names. The inputs are processed from left to right, so a default value expression can be based on earlier inputs. Example:

to proc :inlist [:startvalue first :inlist]

If the procedure is invoked by saying

proc [a b c]

then the variable inlist will have the value [A B C] and the variable startvalue will have the value A. If the procedure is invoked by saying

(proc [a b c] "x)
then \texttt{inlist} will have the value \([A \ B \ C]\) and \texttt{startvalue} will have the value \(X\).

After all the required and optional input can come a single rest input, represented by the following notation:

\[
[:\texttt{inputname}]
\]

This is a rest input rather than an optional input because there is no default value expression. There can be at most one rest input. When the procedure is invoked, the value of this \texttt{inputname} will be a list containing all of the actual inputs provided that were not used for required or optional inputs. Example:

\begin{verbatim}
to proc :in1 [:in2 "foo"] [:in3 "baz"] [:in4]
\end{verbatim}

If this procedure is invoked by saying

\begin{verbatim}
proc "x
\end{verbatim}

then \texttt{in1} has the value \(X\), \texttt{in2} has the value \(FOO\), \texttt{in3} has the value \(BAZ\), and \texttt{in4} has the value \([]\) (the empty list). If it's invoked by saying

\begin{verbatim}
(proc "a "b "c "d "e)
\end{verbatim}

then \texttt{in1} has the value \(A\), \texttt{in2} has the value \(B\), \texttt{in3} has the value \(C\), and \texttt{in4} has the value \([D \ E]\).

The \textit{maximum} number of inputs for a procedure is infinite if a rest input is given; otherwise, it is the number of required inputs plus the number of optional inputs.

The \textit{default} number of inputs for a procedure, which is the number of inputs that it will accept if its invocation is not enclosed in parentheses, is ordinarily equal to the minimum number. If you want a different default number you can indicate that by putting the desired default number as the last thing on the \texttt{TO} line. Example:

\begin{verbatim}
to proc :in1 [:in2 "foo"] [:in3] 3
\end{verbatim}

This procedure has a minimum of one input, a default of three inputs, and an infinite maximum.

Logo responds to the \texttt{TO} command by entering procedure definition mode. The prompt character changes from \(?\) to \(>\) and whatever instructions you type become part of the definition until you type a line containing only the word \texttt{END}.

\texttt{define}

\begin{verbatim}
DEFINE procname text
\end{verbatim}

command. Defines a procedure with name \texttt{procname} and text \texttt{text}. If there is already a procedure with the same name, the new definition replaces the old one. The \texttt{text} input must be a list whose members are lists. The first member is a list of inputs; it looks like a \texttt{TO} line but without the word \texttt{TO}, without the procedure name, and without the colons before input names. In other words, the members of this first sublist are words for the names of required inputs and lists for the names of optional or rest inputs. The remaining sublists of the \texttt{text} input make up the body of the procedure, with one sublist for each instruction line.
of the body. (There is no END line in the text input.) It is an error to redefine a primitive procedure unless the variable REDEFP has the value TRUE.

See [REDEFP], page 91.

text

TEXT procname

outputs the text of the procedure named procname in the form expected by DEFINE: a list of lists, the first of which describes the inputs to the procedure and the rest of which are the lines of its body. The text does not reflect formatting information used when the procedure was defined, such as continuation lines and extra spaces.

fulltext

FULLTEXT procname

outputs a representation of the procedure procname in which formatting information is preserved. If the procedure was defined with TO, EDIT, or LOAD, then the output is a list of words. Each word represents one entire line of the definition in the form output by READWORD, including extra spaces and continuation lines. The last member of the output represents the END line. If the procedure was defined with DEFINE, then the output is a list of lists. If these lists are printed, one per line, the result will look like a definition using TO. Note: the output from FULLTEXT is not suitable for use as input to DEFINE!

See [TO], page 49, [EDIT], page 61, [LOAD], page 63, [DEFINE], page 50.

copydef

COPYDEF newname oldname

command. Makes newname a procedure identical to oldname. The latter may be a primitive. If newname was already defined, its previous definition is lost. If newname was already a primitive, the redefinition is not permitted unless the variable REDEFP has the value TRUE.

Note: dialects of Logo differ as to the order of inputs to COPYDEF. This dialect uses "MAKE order," not "NAME order."

See [REDEFP], page 91, [SAVE], page 62, [PO], page 56, [POT], page 57.

7.2 Variable Definition

make

MAKE varname value

command. Assigns the value value to the variable named varname, which must be a word. Variable names are case-insensitive. If a variable with the same name already exists, the value of that variable is changed. If not, a new global variable is created.

name

NAME value varname (library procedure)

command. Same as MAKE but with the inputs in reverse order.
local

    LOCAL varname
    LOCAL varnamelist
    (LOCAL varname1 varname2 ...)

command. Accepts as inputs one or more words, or a list of words. A variable is created for each of these words, with that word as its name. The variables are local to the currently running procedure. Logo variables follow dynamic scope rules; a variable that is local to a procedure is available to any subprocedure invoked by that procedure. The variables created by LOCAL have no initial value; they must be assigned a value (e.g., with MAKE) before the procedure attempts to read their value.

See [MAKE], page 51.

localmake

    LOCALMAKE varname value (library procedure)

command. Makes the named variable local, like LOCAL, and assigns it the given value, like MAKE.

See [LOCAL], page 52, See [MAKE], page 51.

thing

    THING varname
    :quoted.varname

outputs the value of the variable whose name is the input. If there is more than one such variable, the innermost local variable of that name is chosen. The colon notation is an abbreviation not for THING but for the combination

thing 

so that :FOO means THING "FOO.

global

    GLOBAL varname
    GLOBAL varnamelist
    (GLOBAL varname1 varname2 ...)

command. Accepts as inputs one or more words, or a list of words. A global variable is created for each of these words, with that word as its name. The only reason this is necessary is that you might want to use the "setter" notation SETXYZ for a variable XYZ that does not already have a value; GLOBAL "XYZ makes that legal. Note: If there is currently a local variable of the same name, this command does *not* make Logo use the global value instead of the local one.
7.3 Property Lists

Note: Names of property lists are always case-insensitive. Names of individual properties are case-sensitive or case-insensitive depending on the value of CASEIGNOREDP, which is TRUE by default.

See [CASEIGNOREDP], page 89.

In principle, every possible name is the name of a property list, which is initially empty. So Logo never gives a "no such property list" error, as it would for undefined procedure or variable names. But the primitive procedures that deal with "all" property lists (CONTENTS, PLISTS, etc.) list only nonempty ones. To "erase" a property list [ERASE], page 57 means to make it empty, removing all properties from it.

pprop

PPROP plistname propname value

command. Adds a property to the plistname property list with name propname and value value.

gprop

GPROP plistname propname

outputs the value of the propname property in the plistname property list, or the empty list if there is no such property.

remprop

REMPROP plistname propname

command. Removes the property named propname from the property list named plistname.

plist

PLIST plistname

outputs a list whose odd-numbered members are the names, and whose even-numbered members are the values, of the properties in the property list named plistname. The output is a copy of the actual property list; changing properties later will not magically change a list output earlier by PLIST.

7.4 Workspace Predicates

procedurep

PROCEDUREP name
PROCEDURE? name

outputs TRUE if the input is the name of a procedure.

primitivep

PRIMITIVEP name
PRIMITIVE? name
outputs TRUE if the input is the name of a primitive procedure (one built into Logo). Note that some of the procedures described in this document are library procedures, not primitives.

**definedp**

```lisp
DEFINEDP name
DEFINED? name
```

outputs TRUE if the input is the name of a user-defined procedure, including a library procedure.

**namep**

```lisp
NAMEP name
NAME? name
```

outputs TRUE if the input is the name of a variable.

**plistp**

```lisp
PLISTP name
PLIST? name
```

outputs TRUE if the input is the name of a nonempty property list. (In principle every word is the name of a property list; if you haven’t put any properties in it, PLIST of that name outputs an empty list, rather than giving an error message.)

### 7.5 Workspace Queries

Note: All procedures whose input is indicated as contentslist will accept a single word (taken as a procedure name), a list of words (taken as names of procedures), or a list of three lists as described under the CONTENTS command above.

**contents**

```lisp
CONTENTS
```

outputs a "contents list," i.e., a list of three lists containing names of defined procedures, variables, and property lists respectively. This list includes all unburied named items in the workspace.

**buried**

```lisp
BURIED
```

outputs a contents list including all buried named items in the workspace.

**traced**

```lisp
TRACED
```

outputs a contents list including all traced named items in the workspace.

**stepped**

```lisp
STEPPED
```
outputs a contents list including all stepped named items in the workspace.

**procedures**

PROCEDURES

outputs a list of the names of all unburied user-defined procedures in the workspace. Note that this is a list of names, not a contents list. (However, procedures that require a contents list as input will accept this list.)

**primitives**

PRIMITIVES

outputs a list of the names of all primitive procedures in the workspace. Note that this is a list of names, not a contents list. (However, procedures that require a contents list as input will accept this list.)

**names**

NAMES

outputs a contents list consisting of an empty list (indicating no procedure names) followed by a list of all unburied variable names in the workspace.

**plists**

PLISTS

outputs a contents list consisting of two empty lists (indicating no procedures or variables) followed by a list of all unburied nonempty property lists in the workspace.

**namelist**

NAMELIST varname (library procedure)

NAMELIST varnamelist

outputs a contents list consisting of an empty list followed by a list of the name or names given as input. This is useful in conjunction with workspace control procedures that require a contents list as input.

**pllist**

PLLIST plname (library procedure)

PLLIST plnamelist

outputs a contents list consisting of two empty lists followed by a list of the name or names given as input. This is useful in conjunction with workspace control procedures that require a contents list as input.

See [CONTENTS], page 54.

**arity**

ARITY procedurename
outputs a list of three numbers: the minimum, default, and maximum number of inputs for the procedure whose name is the input. It is an error if there is no such procedure. A maximum of -1 means that the number of inputs is unlimited.

**nodes**

`NODES`

outputs a list of two numbers. The first represents the number of nodes of memory currently in use. The second shows the maximum number of nodes that have been in use at any time since the last invocation of `NODES`. (A node is a small block of computer memory as used by Logo. Each number uses one node. Each non-numeric word uses one node, plus some non-node memory for the characters in the word. Each array takes one node, plus some non-node memory, as well as the memory required by its elements. Each list requires one node per element, as well as the memory within the elements.) If you want to track the memory use of an algorithm, it is best if you invoke `GC` at the beginning of each iteration, since otherwise the maximum will include storage that is unused but not yet collected.

### 7.6 Workspace Inspection

**po**

`PRINTOUT contentslist`

`PO contentslist`

command. Prints to the write stream the definitions of all procedures, variables, and property lists named in the input contents list.

**poall**

`POALL (library procedure)`

command. Prints all unburied definitions in the workspace. Abbreviates `PO CONTENTS`.

See [CONTENTS], page 54.

**pops**

`POPS (library procedure)`

command. Prints the definitions of all unburied procedures in the workspace. Abbreviates `PO PROCEDURES`.

See [PO], page 56, [PROCEDURES], page 55.

**pons**

`PONS (library procedure)`

command. Prints the definitions of all unburied variables in the workspace. Abbreviates `PO NAMES`.

See [PO], page 56, [NAMES], page 55.
popls

POPLS (library procedure)
command. Prints the contents of all unburied nonempty property lists in the workspace.
Abbreviates PO PLISTS.
See [PO], page 56, [PLISTS], page 55.

pon

PON varname (library procedure)
PON varnamelist
command. Prints the definitions of the named variable(s).
Abbreviates PO NAMELIST varname(list).
See [PO], page 56, [NAMELIST], page 55.

popl

POPL plname (library procedure)
POPL plnamelist
command. Prints the definitions of the named property list(s).
Abbreviates PO PLLIST plname(list).
See [PO], page 56, [PLLIST], page 55.

pot

POT contentslist
command. Prints the title lines of the named procedures and the definitions of the named variables and property lists. For property lists, the entire list is shown on one line instead of as a series of PPROP instructions as in PO.
See [PPROP], page 53, [PO], page 56.

pots

POTS (library procedure)
command. Prints the title lines of all unburied procedures in the workspace. Abbreviates POT PROCEDURES.
See [PROCEDURES], page 55.

7.7 Workspace Control

erase

ERASE contentslist
ER contentslist
command. Erases from the workspace the procedures, variables, and property lists named in the input. Primitive procedures may not be erased unless the variable REDEFP has the value TRUE.

See [REDEFP], page 91.

erall

ERALL

command. Erases all unburied procedures, variables, and property lists from the workspace. Abbreviates ERASE CONTENTS.

See [CONTENTS], page 54.

erps

ERPS

command. Erases all unburied procedures from the workspace. Abbreviates ERASE PROCEDURES.

See [ERASE], page 57, [PROCEDURES], page 55.

erns

ERNS

command. Erases all unburied variables from the workspace. Abbreviates ERASE NAMES.

See [ERASE], page 57, [NAMES], page 55.

erpls

ERPLS

command. Erases all unburied property lists from the workspace. Abbreviates ERASE PLISTS.

See [ERASE], page 57, [PLISTS], page 55.

ern

ERN varname (library procedure)
ERN varnamelist

command. Erases from the workspace the variable(s) named in the input. Abbreviates ERASE NAMELIST varname(list).

See [ERASE], page 57, [NAMELIST], page 55.

erpl

ERPL plname (library procedure)
ERPL plnamelist

command. Erases from the workspace the property list(s) named in the input. Abbreviates ERASE PLLIST plname(list).
Chapter 7: Workspace Management

See [ERASE], page 57, [PLLIST], page 55.

bury

\texttt{bury contentslist}

command. Buries the procedures, variables, and property lists named in the input. A buried item is not included in the lists output by \texttt{CONTENTS}, \texttt{PROCEDURES}, \texttt{VARIABLES}, and \texttt{PLISTS}, but is included in the list output by \texttt{BURIED}. By implication, buried things are not printed by \texttt{POALL} or saved by \texttt{SAVE}.

See [CONTENTS], page 54, [PROCEDURES], page 55, [PONS], page 56, [PLISTS], page 55, [POALL], page 56, [SAVE], page 62.

buryall

\texttt{buryall}

(command. Abbreviates \texttt{bury contentslist}).

See [CONTENTS], page 54.

buryname

\texttt{buryname}

\texttt{burynamelist}

(command. Abbreviates \texttt{buryname (library procedure)}).

See [BURY], page 59, [NAMELIST], page 55.

unbury

\texttt{unbury contentslist}

command. Unburies the procedures, variables, and property lists named in the input. That is, the named items will be returned to view in \texttt{CONTENTS}, etc.

See [CONTENTS], page 54.

unburyall

\texttt{unburyall (library procedure)}

(command. Abbreviates \texttt{unbury contentslist}).

See [BURIED], page 54.

unburyname

\texttt{unburyname}

\texttt{unburynamelist}

(command. Abbreviates \texttt{unburyname (library procedure)}).

See [UNBURY], page 59, [NAMELIST], page 55.
buriedp

    BURIEDP contentslist
    BURIED? contentslist

outputs TRUE if the first procedure, variable, or property list named in the contents list is buried, FALSE if not. Only the first thing in the list is tested; the most common use will be with a word as input, naming a procedure, but a contents list is allowed so that you can BURIEDP [[] [variable]] or BURIEDP [[] [] [proplist]].

trace

    TRACE contentslist

command. Marks the named items for tracing. A message is printed whenever a traced procedure is invoked, giving the actual input values, and whenever a traced procedure STOPS or OUTPUTs. A message is printed whenever a new value is assigned to a traced variable using MAKE. A message is printed whenever a new property is given to a traced property list using PPROP.

See [STOP], page 69, [OUTPUT], page 69, [MAKE], page 51, [PPROP], page 53.

untrace

    UNTRACE contentslist

command. Turns off tracing for the named items.

tracedp

    TRACEDP contentslist
    TRACED? contentslist

outputs TRUE if the first procedure, variable, or property list named in the contents list is traced, FALSE if not. Only the first thing in the list is tested; the most common use will be with a word as input, naming a procedure, but a contents list is allowed so that you can TRACEDP [[] [variable]] or TRACEDP [[] [] [proplist]].

step

    STEP contentslist

command. Marks the named items for stepping. Whenever a stepped procedure is invoked, each instruction line in the procedure body is printed before being executed, and Logo waits for the user to type a newline at the terminal. A message is printed whenever a stepped variable name is shadowed because a local variable of the same name is created either as a procedure input or by the LOCAL command.

See [LOCAL], page 52.

unstep

    UNSTEP contentslist

command. Turns off stepping for the named items.
steppedp

STEPPEDP contentslist
STEPPED? contentslist

outputs TRUE if the first procedure, variable, or property list named in the contents list is stepped, FALSE if not. Only the first thing in the list is tested; the most common use will be with a word as input, naming a procedure, but a contents list is allowed so that you can STEPPEDP [[] [variable]] or STEPPEDP [[] [] [proplist]].

edit

EDIT contentslist
ED contentslist
(EDIT)
(ED)

command. If invoked with an input, EDIT writes the definitions of the named items into a temporary file and edits that file, using an editor that depends on the platform you’re using. In wxWidgets, and in the MacOS Classic version, there is an editor built into Logo. In the non-wxWidgets versions for Unix, MacOS X, Windows, and DOS, Logo uses your favorite editor as determined by the EDITOR environment variable. If you don’t have an EDITOR variable, edits the definitions using jove. If invoked without an input, EDIT edits the same file left over from a previous EDIT or EDITFILE instruction. When you leave the editor, Logo reads the revised definitions and modifies the workspace accordingly. It is not an error if the input includes names for which there is no previous definition.

If there is a variable LOADNOISILY whose value is TRUE, then, after leaving the editor, TO commands in the temporary file print ‘procname defined’ (where procname is the name of the procedure being defined); if LOADNOISILY is FALSE or undefined, TO commands in the file are carried out silently.

If there is an environment variable called TEMP, then Logo uses its value as the directory in which to write the temporary file used for editing.

Exceptionally, the EDIT command can be used without its default input and without parentheses provided that nothing follows it on the instruction line.

See [LOADNOISILY], page 90 , See [EDITFILE], page 61 .

editfile

EDITFILE filename

command. Starts the Logo editor, like EDIT, but instead of editing a temporary file it edits the file specified by the input. When you leave the editor, Logo reads the revised file, as for EDIT. EDITFILE also remembers the filename, so that a subsequent EDIT command with no input will re-edit the same file.

EDITFILE is intended as an alternative to LOAD and SAVE. You can maintain a workspace file yourself, controlling the order in which definitions appear, maintaining comments in the file, and so on.
In the wxWidgets version, EDITFILE asks whether or not you want to load the file into Logo when you finish editing. This allows you to use EDITFILE to edit data files without leaving Logo.

**edall**

EDALL (library procedure)

command. Abbreviates EDIT CONTENTS.

See [CONTENTS], page 54.

**edps**

EDPS (library procedure)

command. Abbreviates EDIT PROCEDURES.

See [EDIT], page 61, [PROCEDURES], page 55.

**edns**

EDNS (library procedure)

command. Abbreviates EDIT NAMES.

See [EDIT], page 61, [NAMES], page 55.

**edpls**

EDPLS (library procedure)

command. Abbreviates EDIT PLISTS.

See [EDIT], page 61, [PLISTS], page 55.

**edn**

EDN varname (library procedure)

EDN varnamelist

command. Abbreviates EDIT NAMELIST varname(list).

See [EDIT], page 61, [NAMELIST], page 55.

**edpl**

EDPL plname (library procedure)

EDPL plnamelist

command. Abbreviates EDIT PLLIST plname(list).

See [EDIT], page 61, [PLLIST], page 55.

**save**

SAVE filename

command. Saves the definitions of all unburied procedures, variables, and nonempty property lists in the named file. Equivalent to
to save :filename
local "oldwriter
make "oldwriter writer
openwrite :filename
setwrite :filename
poall
setwrite :oldwriter
close :filename
end

Exceptionally, \texttt{SAVE} can be used with no input and without parentheses if it is the last thing on the command line. In this case, the filename from the most recent \texttt{LOAD} or \texttt{SAVE} command will be used. (It is an error if there has been no previous \texttt{LOAD} or \texttt{SAVE}.)

\textbf{savel}

\texttt{SAVEL contentslist filename} (library procedure)

command. Saves the definitions of the procedures, variables, and property lists specified by \texttt{contentslist} to the file named \texttt{filename}.

\textbf{load}

\texttt{LOAD filename}

command. Reads instructions from the named file and executes them. The file can include procedure definitions with \texttt{TO}, and these are accepted even if a procedure by the same name already exists. If the file assigns a list value to a variable named \texttt{STARTUP}, then that list is run as an instructionlist after the file is loaded. If there is a variable \texttt{LOADNOISILY} whose value is \texttt{TRUE}, then \texttt{TO} commands in the file print \texttt{`procname defined'} (where \texttt{procname} is the name of the procedure being defined); if \texttt{LOADNOISILY} is \texttt{FALSE} or undefined, \texttt{TO} commands in the file are carried out silently.

See [\texttt{STARTUP}], page 91, See [\texttt{LOADNOISILY}], page 90.

\textbf{cslsload}

\texttt{CSLSLOAD name}

command. Loads the named file, like \texttt{LOAD}, but from the directory containing the Computer Science Logo Style programs instead of the current user’s directory.

See [\texttt{LOAD}], page 63.

\textbf{help}

\texttt{HELP name}

(\texttt{HELP})

command. Prints information from the reference manual about the primitive procedure named by the input. With no input, lists all the primitives about which help is available. If there is an environment variable \texttt{LOGOHELP}, then its value is taken as the directory in which to look for help files, instead of the default help directory.
If HELP is called with the name of a defined procedure for which there is no help file, it will print the title line of the procedure followed by lines from the procedure body that start with semicolon, stopping when a non-semicolon line is seen.

Exceptionally, the HELP command can be used without its default input and without parentheses provided that nothing follows it on the instruction line.

seteditor

```
seteditor path
```

command. Tells Logo to use the specified program as its editor instead of the default editor. The format of a path depends on your operating system.

setlibloc

```
setlibloc path
```

command. Tells Logo to use the specified directory as its library instead of the default. (Note that many Logo "primitive" procedures are actually found in the library, so they may become unavailable if your new library does not include them!) The format of a path depends on your operating system.

setcslsloc

```
setcslsloc path
```

command. Tells Logo to use the specified directory for the CSLSLOAD command, instead of the default directory. The format of a path depends on your operating system.

See [CSLSLOAD], page 63.

sethelploc

```
sethelploc path
```

command. Tells Logo to look in the specified directory for the information provided by the HELP command, instead of the default directory. The format of a path depends on your operating system.

settemploc

```
settemploc path
```

command. Tells Logo to write editor temporary files in the specified directory rather than in the default directory. You must have write permission for this directory. The format of a path depends on your operating system.

gc

```
gc
  (gc anything)
```

command. Runs the garbage collector, reclaiming unused nodes. Logo does this when necessary anyway, but you may want to use this command to control exactly when Logo does it. In particular, the numbers output by the NODES operation will not be very meaningful
unless garbage has been collected. Another reason to use GC is that a garbage collection takes a noticeable fraction of a second, and you may want to schedule collections for times before or after some time-critical animation. If invoked with an argument (of any value), GC runs a full garbage collection, including GCTWA (Garbage Collect Truly Worthless Atoms, which means that it removes from Logo’s memory words that used to be procedure or variable names but aren’t any more); without an argument, GC does a generational garbage collection, which means that only recently created nodes are examined. (The latter is usually good enough.)

.setsegmentsize

.SETSEGMENTSIZE num

command. Sets the number of nodes that Logo allocates from the operating system at once to num, which must be a positive integer. The name is dotted because bad things will happen if you use a number that’s too small or too large for your computer. The initial value is 16,000 for most systems, but is smaller for 68000-based Macs. Making it larger will speed up computations (by reducing the number of garbage collections) at the cost of allocating more memory than necessary.
8 Control Structures

8.1 Control

Note: in the following descriptions, an instructionlist can be a list or a word. In the latter case, the word is parsed into list form before it is run. Thus, RUN READWORD or RUN READLIST will work. The former is slightly preferable because it allows for a continued line (with ~) that includes a comment (with ;) on the first line.

A tf input must be the word TRUE, the word FALSE, or a list. If it’s a list, then it must be a Logo expression, which will be evaluated to produce a value that must be TRUE or FALSE. The comparisons with TRUE and FALSE are always case-insensitive.

A runlist can consist of either a single expression (that produces a value) or zero or more instructions (that do something, rather than output a value), depending on the context:

```
PRINT IFELSE :X<0 ["NEGATIVE"] ["POSITIVE"] ; one value in each case
REPEAT 4 [PRINT "A PRINT "B] ; two instructions
```

run

RUN instructionlist
	command or operation. Runs the Logo instructions in the input list; outputs if the list contains an expression that outputs.

See [READWORD], page 20, [READLIST], page 20.

runresult

RUNRESULT instructionlist
	runs the instructions in the input; outputs an empty list if those instructions produce no output, or a list whose only member is the output from running the input instructionlist. Useful for inventing command-or-operation control structures:

```
local "result
make "result runresult [something]
if emptyp :result [stop]
output first :result
```

repeat

REPEAT num instructionlist
	command. Runs the instructionlist repeatedly, num times.

forever

FOREVER instructionlist
	command. Runs the "instructionlist" repeatedly, until something inside the instructionlist (such as STOP or THROW) makes it stop.

See [STOP], page 69, See [THROW], page 69.
repcount

REPCOUNT

outputs the repetition count of the innermost current REPEAT or FOREVER, starting from 1. If no REPEAT or FOREVER is active, outputs –1.

The abbreviation # can be used for REPCOUNT unless the REPEAT is inside the template input to a higher order procedure such as FOREACH, in which case # has a different meaning.

if

IF tf instructionlist
(IF tf instructionlist1 instructionlist2)

command. If the first input has the value TRUE, then IF runs the second input. If the first input has the value FALSE, then IF does nothing. (If given a third input, IF acts like IFELSE, as described below.) It is an error if the first input is not either TRUE or FALSE.

For compatibility with earlier versions of Logo, if an IF instruction is not enclosed in parentheses, but the first thing on the instruction line after the second input expression is a literal list (i.e., a list in square brackets), the IF is treated as if it were IFELSE, but a warning message is given. If this aberrant IF appears in a procedure body, the warning is given only the first time the procedure is invoked in each Logo session.

ifelse

IFELSE tf instructionlist1 instructionlist2

command or operation. If the first input has the value TRUE, then IFELSE runs the second input. If the first input has the value FALSE, then IFELSE runs the third input. IFELSE outputs a value if the instructionlist contains an expression that outputs a value.

test

TEST tf

command. Remembers its input, which must be TRUE or FALSE, for use by later IFTRUE or IFFALSE instructions. The effect of TEST is local to the procedure in which it is used; any corresponding IFTRUE or IFFALSE must be in the same procedure or a subprocedure.

See [IFFALSE], page 68.

iftrue

IFTRUE instructionlist
IFT instructionlist

command. Runs its input if the most recent TEST instruction had a TRUE input. The TEST must have been in the same procedure or a superprocedure.

iffalse

IFFALSE instructionlist
IFF instructionlist
command. Runs its input if the most recent TEST instruction had a FALSE input. The TEST must have been in the same procedure or a superprocedure.

See [TEST], page 68.

**stop**

    STOP

command. Ends the running of the procedure in which it appears. Control is returned to the context in which that procedure was invoked. The stopped procedure does not output a value.

**output**

    OUTPUT value
    OP value

command. Ends the running of the procedure in which it appears. That procedure outputs the value value to the context in which it was invoked. Don’t be confused: OUTPUT itself is a command, but the procedure that invokes OUTPUT is an operation.

**catch**

    CATCH tag instructionlist

command or operation. Runs its second input. Outputs if that instructionlist outputs. If, while running the instructionlist, a THROW instruction is executed with a tag equal to the first input (case-insensitive comparison), then the running of the instructionlist is terminated immediately. In this case the CATCH outputs if a value input is given to THROW. The tag must be a word.

If the tag is the word ERROR, then any error condition that arises during the running of the instructionlist has the effect of THROW "ERROR instead of printing an error message and returning to toplevel. The CATCH does not output if an error is caught. Also, during the running of the instructionlist, the variable ERRACT is temporarily unbound. (If there is an error while ERRACT has a value, that value is taken as an instructionlist to be run after printing the error message. Typically the value of ERRACT, if any, is the list [PAUSE].)

See [ERROR], page 70, [ERRACT], page 89, [PAUSE], page 70.

**throw**

    THROW tag
    (THROW tag value)

command. Must be used within the scope of a CATCH with an equal tag. Ends the running of the instructionlist of the CATCH. If THROW is used with only one input, the corresponding CATCH does not output a value. If THROW is used with two inputs, the second provides an output for the CATCH.

THROW "TOPLEVEL can be used to terminate all running procedures and interactive pauses, and return to the toplevel instruction prompt. Typing the system interrupt character
THROW "ERROR can be used to generate an error condition. If the error is not caught, it prints a message (THROW "ERROR) with the usual indication of where the error (in this case the THROW) occurred. If a second input is used along with a tag of ERROR, that second input is used as the text of the error message instead of the standard message. Also, in this case, the location indicated for the error will be, not the location of the THROW, but the location where the procedure containing the THROW was invoked. This allows user-defined procedures to generate error messages as if they were primitives. Note: in this case the corresponding CATCH "ERROR, if any, does not output, since the second input to THROW is not considered a return value.

THROW "SYSTEM immediately leaves Logo, returning to the operating system, without printing the usual parting message and without deleting any editor temporary file written by EDIT.

See [EDIT], page 61.

error

ERROR

outputs a list describing the error just caught, if any. If there was not an error caught since the last use of ERROR, the empty list will be output. The error list contains four members: an integer code corresponding to the type of error, the text of the error message (as a single word including spaces), the name of the procedure in which the error occurred, and the instruction line on which the error occurred.

pause

PAUSE

command or operation. Enters an interactive pause. The user is prompted for instructions, as at top level, but with a prompt that includes the name of the procedure in which PAUSE was invoked. Local variables of that procedure are available during the pause. PAUSE outputs if the pause is ended by a CONTINUE with an input.

If the variable ERRACT exists, and an error condition occurs, the contents of that variable are run as an instruction list. Typically ERRACT is given the value [PAUSE] so that an interactive pause will be entered in the event of an error. This allows the user to check values of local variables at the time of the error.

Typing the system quit character (ALT-S for wxWidgets; otherwise normally CONTROL-C for Unix, CONTROL-Q for DOS, or COMMAND-PERIOD for Mac) will also enter a pause.

See [ERRACT], page 89.

continue

CONTINUE value

CO value
(CONTINUE)
(CO)

command. Ends the current interactive pause, returning to the context of the PAUSE invocation that began it. If CONTINUE is given an input, that value is used as the output from the PAUSE. If not, the PAUSE does not output.

Exceptionally, the CONTINUE command can be used without its default input and without parentheses provided that nothing follows it on the instruction line.

**wait**

WAIT time

command. Delays further execution for time 60ths of a second. Also causes any buffered characters destined for the terminal to be printed immediately. WAIT 0 can be used to achieve this buffer flushing without actually waiting.

**bye**

BYE

command. Exits from Logo; returns to the operating system.

**.maybeoutput**

.MAYBEOUTPUT value (special form)

works like OUTPUT except that the expression that provides the input value might not, in fact, output a value, in which case the effect is like STOP. This is intended for use in control structure definitions, for cases in which you don’t know whether or not some expression produces a value. Example:

```
to invoke :function [:inputs] 2
  .maybeoutput apply :function :inputs
end

? (invoke "print "a "b "c)
  a b c
? print (invoke "word "a "b "c)
  abc
```

This is an alternative to RUNRESULT. It’s fast and easy to use, at the cost of being an exception to Logo’s evaluation rules. (Ordinarily, it should be an error if the expression that’s supposed to provide an input to something doesn’t have a value.)

See [OUTPUT], page 69, [STOP], page 69, [RUNRESULT], page 67.

**goto**

GOTO word

command. Looks for a TAG command with the same input in the same procedure, and continues running the procedure from the location of that TAG. It is meaningless to use GOTO outside of a procedure.
tag

TAG quoted.word command. Does nothing. The input must be a literal word following a quotation mark ("), not the result of a computation. Tags are used by the GOTO command.

ignore

IGNORE value (library procedure) command. Does nothing. Used when an expression is evaluated for a side effect and its actual value is unimportant.

‘ list (library procedure)

outputs a list equal to its input but with certain substitutions. If a member of the input list is the word ‘,’ (comma) then the following member should be an instructionlist that produces an output when run. That output value replaces the comma and the instructionlist. If a member of the input list is the word ‘@’ (comma atsign) then the following member should be an instructionlist that outputs a list when run. The members of that list replace the ‘,@’ and the instructionlist. Example:

show ‘[foo baz ,[bf [a b c]] garply ,@[bf [a b c]]]

will print

[foo baz [b c] garply b c]

A word starting with ‘,’ or ‘,@’ is treated as if the rest of the word were a one-word list, e.g., ‘,:foo’ is equivalent to ‘,[:Foo]’.

A word starting with ‘",’ (quote comma) or ‘,:’ (colon comma) becomes a word starting with ‘”’ or ‘:’ but with the result of running the substitution (or its first word, if the result is a list) replacing what comes after the comma.

Backquotes can be nested. Substitution is done only for commas at the same depth as the backquote in which they are found:

? show ‘[a ‘[b ,[1+2] ,[foo ,[1+3] d] e] f]
[a ‘ [b , [1+2] , [foo 4 d] e] f]

?make "name1 "x
?make "name2 "y
? show ‘[a ‘[b ,,:name1 ,",:name2 d] e]
[a ‘ [b , [:x] , ["y] d] e]

for

FOR forcontrol instructionlist (library procedure) command. The first input must be a list containing three or four members: (1) a word, which will be used as the name of a local variable; (2) a word or list that will be evaluated as
by RUN to determine a number, the starting value of the variable; (3) a word or list that will be evaluated to determine a number, the limit value of the variable; (4) an optional word or list that will be evaluated to determine the step size. If the fourth member is missing, the step size will be 1 or \(-1\) depending on whether the limit value is greater than or less than the starting value, respectively.

The second input is an instruction list. The effect of FOR is to run that instruction list repeatedly, assigning a new value to the control variable (the one named by the first member of the \(\text{forcontrol} \) list) each time. First the starting value is assigned to the control variable. Then the value is compared to the limit value. FOR is complete when the sign of \((\text{current} - \text{limit})\) is the same as the sign of the step size. (If no explicit step size is provided, the instruction list is always run at least once. An explicit step size can lead to a zero-trip FOR, e.g., FOR \([I\ 1\ 0\ 1]\ \ldots\). Otherwise, the instruction list is run, then the step is added to the current value of the control variable and FOR returns to the comparison step.

\[
? \textbf{for} \ [i\ 2\ 7\ 1.5] \ [\text{print} :i]
2
3.5
5
6.5
?
\]

See [RUN], page 67.

**do.while**

DO.WHILE instruction list tfexpression (library procedure)

command. Repeatedly evaluates the \(\text{instruction list}\) as long as the evaluated \(\text{tfexpression}\) remains TRUE. Evaluates the first input first, so the \(\text{instruction list}\) is always run at least once. The \(\text{tfexpression}\) must be an expression list whose value when evaluated is TRUE or FALSE.

**while**

WHILE tfexpression instruction list (library procedure)

command. Repeatedly evaluates the \(\text{instruction list}\) as long as the evaluated \(\text{tfexpression}\) remains TRUE. Evaluates the first input first, so the \(\text{instruction list}\) may never be run at all. The \(\text{tfexpression}\) must be an expression list whose value when evaluated is TRUE or FALSE.

**do.until**

DO.UNTIL instruction list tfexpression (library procedure)

command. Repeatedly evaluates the \(\text{instruction list}\) as long as the evaluated \(\text{tfexpression}\) remains FALSE. Evaluates the first input first, so the \(\text{instruction list}\) is always run at least once. The \(\text{tfexpression}\) must be an expression list whose value when evaluated is TRUE or FALSE.

**until**

UNTIL tfexpression instruction list (library procedure)
command. Repeatedly evaluates the \textit{instructionlist} as long as the evaluated \textit{tfexpression} remains \texttt{FALSE}. Evaluates the first input first, so the \textit{instructionlist} may never be run at all. The \textit{tfexpression} must be an expressionlist whose value when evaluated is \texttt{TRUE} or \texttt{FALSE}.

\textbf{case}

\textbf{CASE} value clauses (library procedure)

command or operation. The second input is a list of lists (clauses); each clause is a list whose first element is either a list of values or the word \texttt{ELSE} and whose butfirst is a Logo expression or instruction. \textbf{CASE} examines the clauses in order. If a clause begins with the word \texttt{ELSE} (upper or lower case), then the butfirst of that clause is evaluated and \textbf{CASE} outputs its value, if any. If the first input to \textbf{CASE} is a member of the first element of a clause, then the butfirst of that clause is evaluated and \textbf{CASE} outputs its value, if any. If neither of these conditions is met, then \textbf{CASE} goes on to the next clause. If no clause is satisfied, \textbf{CASE} does nothing. Example:

\begin{verbatim}
to vowelp :letter
  output case :letter [ [[a e i o u] "true"] [else "false"] ]
end
\end{verbatim}

\textbf{cond}

\textbf{COND} clauses (library procedure)

command or operation. The input is a list of lists (clauses); each clause is a list whose first element is either an expression whose value is \texttt{TRUE} or \texttt{FALSE}, or the word \texttt{ELSE}, and whose butfirst is a Logo expression or instruction. \textbf{COND} examines the clauses in order. If a clause begins with the word \texttt{ELSE} (upper or lower case), then the butfirst of that clause is evaluated and \textbf{CASE} outputs its value, if any. Otherwise, the first element of the clause is evaluated; the resulting value must be \texttt{TRUE} or \texttt{FALSE}. If it’s \texttt{TRUE}, then the butfirst of that clause is evaluated and \textbf{COND} outputs its value, if any. If the value is \texttt{FALSE}, then \textbf{COND} goes on to the next clause. If no clause is satisfied, \textbf{COND} does nothing. Example:

\begin{verbatim}
to evens :numbers ; select even numbers from a list
  op cond [ [emptyp :numbers] []
            [[evenp first :numbers] ; assuming EVENP is defined
             fput first :numbers evens butfirst :numbers]
            [else evens butfirst :numbers] ]
end
\end{verbatim}

\section*{8.2 Template-based Iteration}

The procedures in this section are iteration tools based on the idea of a \textit{template}. This is a generalization of an instruction list or an expression list in which \textit{slots} are provided for the tool to insert varying data. Four different forms of template can be used.

The most commonly used form for a template is ‘\texttt{explicit-slot}’ form, or ‘\texttt{question mark}’ form. Example:

\begin{verbatim}
? show map [? * ?] [2 3 4 5]
[4 9 16 25]
\end{verbatim}
In this example, the \textbf{MAP} tool evaluated the template \([? * ?]\) repeatedly, with each of the members of the data list \([2 3 4 5]\) substituted in turn for the question marks. The same value was used for every question mark in a given evaluation. Some tools allow for more than one datum to be substituted in parallel; in these cases the slots are indicated by \(?1\) for the first datum, \(?2\) for the second, and so on:

\[
\text{? show (map \[(word ?1 ?2 ?1)\] [a b c] [d e f])}
\]

\[
[ada beb cfc]
\]

If the template wishes to compute the datum number, the form \((? 1)\) is equivalent to \(?1\), so \((? ?1)\) means the datum whose number is given in datum number 1. Some tools allow additional slot designations, as shown in the individual descriptions.

The second form of template is the \textit{‘named-procedure’} form. If the template is a word rather than a list, it is taken as the name of a procedure. That procedure must accept a number of inputs equal to the number of parallel data slots provided by the tool; the procedure is applied to all of the available data in order. That is, if data \(?1\) through \(?3\) are available, the template \textit{“PROC} is equivalent to \textit{[PROC ?1 ?2 ?3]}.

\[
\text{? show (map \"word [a b c] [d e f])}
\]

\[
[ad be cf]
\]

\textit{to dotprod :a :b ; vector dot product}
\textit{op apply \"sum (map \"product :a :b)\}
\textit{end}

The third form of template is \textit{‘named-slot’} or \textit{‘lambda’} form. This form is indicated by a template list containing more than one member, whose first member is itself a list. The first member is taken as a list of names; local variables are created with those names and given the available data in order as their values. The number of names must equal the number of available data. This form is needed primarily when one iteration tool must be used within the template list of another, and the \textit{?} notation would be ambiguous in the inner template. Example:

\textit{to matmul :m1 :m2 [:tm2 transpose :m2] ; multiply two matrices}
\textit{end}

The fourth form is \textit{‘procedure text’} form, a variant of lambda form. In this form, the template list contains at least two members, all of which are lists. This is the form used by the \texttt{DEFINE} and \texttt{TEXT} primitives, and \texttt{APPLY} accepts it so that the text of a defined procedure can be used as a template.

\textbf{Note:} The fourth form of template is interpreted differently from the others, in that Logo considers it to be an independent defined procedure for the purposes of \texttt{OUTPUT} and \texttt{STOP}. For example, the following two instructions are identical:
although the first instruction is in named-slot form and the second is in procedure-text form. The named-slot form can be understood as telling Logo to evaluate the expression :x+3 in place of the entire invocation of apply, with the variable x temporarily given the value 5. The procedure-text form can be understood as invoking the procedure

to foo :x
output :x+3
end

with input 5, but without actually giving the procedure a name. If the use of OUTPUT were interchanged in these two examples, we’d get errors:

? print apply [[x] output :x+3] [5]
Can only use output inside a procedure
? print apply [[x] [:x+3]] [5]
You don’t say what to do with 8

The named-slot form can be used with STOP or OUTPUT inside a procedure, to stop the enclosing procedure.

The following iteration tools are extended versions of the ones in Appendix B of the book Computer Science Logo Style, Volume 3: Advanced Topics by Brian Harvey [MIT Press, 1987]. The extensions are primarily to allow for variable numbers of inputs.

apply

APPLY template inputlist

command or operation. Runs the template, filling its slots with the members of inputlist. The number of members in inputlist must be an acceptable number of slots for template. It is illegal to apply the primitive TO as a template, but anything else is okay. APPLY outputs what template outputs, if anything.

See [TO], page 49 .

invoke

INVOKE template input (library procedure)
(INVOKE template input1 input2 ...)

command or operation. Exactly like APPLY except that the inputs are provided as separate expressions rather than in a list.

foreach

FOREACH data template (library procedure)
(FOREACH data1 data2 ... template)
command. Evaluates the template list repeatedly, once for each member of the data list. If more than one data list are given, each of them must be the same length. (The data inputs can be words, in which case the template is evaluated once for each character.)

In a template, the symbol ?REST represents the portion of the data input to the right of the member currently being used as the ? slot-filler. That is, if the data input is [A B C D E] and the template is being evaluated with ? replaced by B, then ?REST would be replaced by [C D E]. If multiple parallel slots are used, then (?REST 1) goes with ?1, etc.

In a template, the symbol # represents the position in the data input of the member currently being used as the ? slot-filler. That is, if the data input is [A B C D E] and the template is being evaluated with ? replaced by B, then # would be replaced by 2.

**map**

MAP template data (library procedure)

(MAP template data1 data2 ...)

outputs a word or list, depending on the type of the data input, of the same length as that data input. (If more than one data input are given, the output is of the same type as data1.) Each member of the output is the result of evaluating the template list, filling the slots with the corresponding member(s) of the data input(s). (All data inputs must be the same length.) In the case of a word output, the results of the template evaluation must be words, and they are concatenated with WORD.

In a template, the symbol ?REST represents the portion of the data input to the right of the member currently being used as the ? slot-filler. That is, if the data input is [A B C D E] and the template is being evaluated with ? replaced by B, then ?REST would be replaced by [C D E]. If multiple parallel slots are used, then (?REST 1) goes with ?1, etc.

In a template, the symbol # represents the position in the data input of the member currently being used as the ? slot-filler. That is, if the data input is [A B C D E] and the template is being evaluated with ? replaced by B, then # would be replaced by 2.

See [WORD], page 9.

**map.se**

MAP.SE template data (library procedure)

(MAP.SE template data1 data2 ...)

outputs a list formed by evaluating the template list repeatedly and concatenating the results using SENTENCE. That is, the members of the output are the members of the results of the evaluations. The output list might, therefore, be of a different length from that of the data input(s). (If the result of an evaluation is the empty list, it contributes nothing to the final output.) The data inputs may be words or lists.

In a template, the symbol ?REST represents the portion of the data input to the right of the member currently being used as the ? slot-filler. That is, if the data input is [A B C D E] and the template is being evaluated with ? replaced by B, then ?REST would be replaced by [C D E]. If multiple parallel slots are used, then (?REST 1) goes with ?1, etc.
In a template, the symbol \# represents the position in the data input of the member currently being used as the ? slot-filler. That is, if the data input is [A B C D E] and the template is being evaluated with ? replaced by B, then \# would be replaced by 2.

See [SENTENCE], page 9.

**filter**

FILTER tftemplate data (library procedure)

outputs a word or list, depending on the type of the data input, containing a subset of the members (for a list) or characters (for a word) of the input. The template is evaluated once for each member or character of the data, and it must produce a TRUE or FALSE value. If the value is TRUE, then the corresponding input constituent is included in the output.

```lisp
 ? print filter "vowelp "elephant
  eea
 ?
```

In a template, the symbol ?REST represents the portion of the data input to the right of the member currently being used as the ? slot-filler. That is, if the data input is [A B C D E] and the template is being evaluated with ? replaced by B, then ?REST would be replaced by [C D E].

In a template, the symbol \# represents the position in the data input of the member currently being used as the ? slot-filler. That is, if the data input is [A B C D E] and the template is being evaluated with ? replaced by B, then \# would be replaced by 2.

**find**

FIND tftemplate data (library procedure)

outputs the first constituent of the data input (the first member of a list, or the first character of a word) for which the value produced by evaluating the template with that constituent in its slot is TRUE. If there is no such constituent, the empty list is output.

In a template, the symbol ?REST represents the portion of the data input to the right of the member currently being used as the ? slot-filler. That is, if the data input is [A B C D E] and the template is being evaluated with ? replaced by B, then ?REST would be replaced by [C D E].

In a template, the symbol \# represents the position in the data input of the member currently being used as the ? slot-filler. That is, if the data input is [A B C D E] and the template is being evaluated with ? replaced by B, then \# would be replaced by 2.

**reduce**

REDUCE template data (library procedure)

outputs the result of applying the template to accumulate the members of the data input. The template must be a two-slot function. Typically it is an associative function name like SUM. If the data input has only one constituent (member in a list or character in a word), the output is that constituent. Otherwise, the template is first applied with ?1 filled with the next-to-last constituent and ?2 with the last constituent. Then, if there are more
constituents, the template is applied with ?1 filled with the next constituent to the left and ?2 with the result from the previous evaluation. This process continues until all constituents have been used. The data input may not be empty.

Note: If the template is, like SUM, the name of a procedure that is capable of accepting arbitrarily many inputs, it is more efficient to use APPLY instead of REDUCE. The latter is good for associative procedures that have been written to accept exactly two inputs:

```lisp
to max :a :b
  output ifelse :a > :b [:a] [:b]
end

print reduce "max [...]
```

Alternatively, REDUCE can be used to write MAX as a procedure that accepts any number of inputs, as SUM does:

```lisp
to max [:inputs] 2
  if emptyp :inputs ~
    [(throw "error [not enough inputs to max]])
  output reduce [ifelse ?1 > ?2 [?1] [?2]] :inputs
end
```

See [SUM], page 29, [APPLY], page 76.

**crossmap**

CROSSMAP template listlist (library procedure)

(CROSSMAP template data1 data2 ...)

outputs a list containing the results of template evaluations. Each data list contributes to a slot in the template; the number of slots is equal to the number of data list inputs. As a special case, if only one data list input is given, that list is taken as a list of data lists, and each of its members contributes values to a slot. CROSSMAP differs from MAP in that instead of taking members from the data inputs in parallel, it takes all possible combinations of members of data inputs, which need not be the same length.

```lisp
? show (crossmap [word ?1 ?2] [a b c] [1 2 3 4])
[a1 a2 a3 a4 b1 b2 b3 b4 c1 c2 c3 c4]
```

For compatibility with the version in the first edition of CSLS\(^1\), CROSSMAP templates may use the notation :1 instead of ?1 to indicate slots.

See [MAP], page 77.

**cascade**

CASCADE endtest template startvalue (library procedure)

(CASCADE endtest tmp1 sv1 tmp2 sv2 ...)

(CASCADE endtest tmp1 sv1 tmp2 sv2 ... finaltemplate)

\(^1\) Computer Science Logo Style
outputs the result of applying a template (or several templates, as explained below) repeatedly, with a given value filling the slot the first time, and the result of each application filling the slot for the following application.

In the simplest case, CASCADE has three inputs. The second input is a one-slot expression template. That template is evaluated some number of times (perhaps zero). On the first evaluation, the slot is filled with the third input; on subsequent evaluations, the slot is filled with the result of the previous evaluation. The number of evaluations is determined by the first input. This can be either a nonnegative integer, in which case the template is evaluated that many times, or a predicate expression template, in which case it is evaluated (with the same slot filler that will be used for the evaluation of the second input) repeatedly, and the CASCADE evaluation continues as long as the predicate value is FALSE. (In other words, the predicate template indicates the condition for stopping.)

If the template is evaluated zero times, the output from CASCADE is the third (startvalue) input. Otherwise, the output is the value produced by the last template evaluation.

CASCADE templates may include the symbol # to represent the number of times the template has been evaluated. This slot is filled with 1 for the first evaluation, 2 for the second, and so on.

? show cascade 5 [lput # ?] []
[1 2 3 4 5]
? show cascade [vowelp first ?] [bf ?] "springing"
? show cascade 5 [# * ?] 1
120
?

Several cascaded results can be computed in parallel by providing additional template-startvalue pairs as inputs to CASCADE. In this case, all templates (including the endtest template, if used) are multi-slot, with the number of slots equal to the number of pairs of inputs. In each round of evaluations, ?2, for example, represents the result of evaluating the second template in the previous round. If the total number of inputs (including the first endtest input) is odd, then the output from CASCADE is the final value of the first template. If the total number of inputs is even, then the last input is a template that is evaluated once, after the end test is satisfied, to determine the output from CASCADE.

to fibonacci :n
output (cascade :n [?1 + ?2] 1 [?1] 0)
end

to piglatin :word
output (cascade [vowelp first ?] ~
[word bf ? first ?] ~
:word ~
[word ? "ay])
end
cascade.2

CASCADE.2 endtest temp1 startval1 temp2 startval2 (library procedure)
outputs the result of invoking CASCADE with the same inputs. The only difference is that
the default number of inputs is five instead of three.

transfer

TRANSFER endtest template inbasket (library procedure)
outputs the result of repeated evaluation of the template. The template is evaluated once
for each member of the list inbasket. TRANSFER maintains an outbasket that is initially
the empty list. After each evaluation of the template, the resulting value becomes the new
outbasket.

In the template, the symbol ?IN represents the current member from the inbasket; the
symbol ?OUT represents the entire current outbasket. Other slot symbols should not be
used.

If the first (endtest) input is an empty list, evaluation continues until all inbasket mem-
bers have been used. If not, the first input must be a predicate expression template, and
evaluation continues until either that template’s value is TRUE or the inbasket is used up.
A macro is a special kind of procedure whose output is evaluated as Logo instructions in the context of the macro’s caller. `.MACRO` is exactly like `TO` except that the new procedure becomes a macro; `.DEFMACRO` is exactly like `DEFINE` with the same exception.

Macros are useful for inventing new control structures comparable to `REPEAT`, `IF`, and so on. Such control structures can almost, but not quite, be duplicated by ordinary Logo procedures. For example, here is an ordinary procedure version of `REPEAT`:

```
to my.repeat :num :instructions
  if :num=0 [stop]
  run :instructions
  my.repeat :num-1 :instructions
end
```

This version works fine for most purposes, e.g.,

```
my.repeat 5 [print "hello"
```

But it doesn’t work if the instructions to be carried out include `OUTPUT`, `STOP`, or `LOCAL`. For example, consider this procedure:

```
to example
  print [Guess my secret word. You get three guesses.]
  repeat 3 [type "|?? | ~
    if readword = "secret [pr "Right! stop]]
  print [Sorry, the word was "secret"]
end
```

This procedure works as written, but if `MY.REPEAT` is used instead of `REPEAT`, it won’t work because the `STOP` will stop `MY.REPEAT` instead of stopping `EXAMPLE` as desired.

The solution is to make `MY.REPEAT` a macro. Instead of actually carrying out the computation, a macro must return a list containing Logo instructions. The contents of that list are evaluated as if they appeared in place of the call to the macro. Here’s a macro version of `REPEAT`:

```
.macro my.repeat :num :instructions
  if :num=0 [output []]
  output sentence :instructions ~
      (list "my.repeat :num-1 :instructions)
end
```

Every macro is an operation — it must always output something. Even in the base case, `MY.REPEAT` outputs an empty instruction list. To show how `MY.REPEAT` works, let’s take the example
my.repeat 5 [print "hello]
For this example, MY.REPEAT will output the instruction list

[print "hello my.repeat 4 [print "hello]]

Logo then executes these instructions in place of the original invocation of MY.REPEAT; this prints hello once and invokes another repetition.

The technique just shown, although fairly easy to understand, has the defect of slowness because each repetition has to construct an instruction list for evaluation. Another approach is to make MY.REPEAT a macro that works just like the non-macro version unless the instructions to be repeated include OUTPUT or STOP:

.macro my.repeat :num :instructions
  catch "repeat.catchtag ~
  [op repeat.done runresult [repeat1 :num :instructions]]
  op []
end

to repeat1 :num :instructions
  if :num=0 [throw "repeat.catchtag]
  run :instructions
  .maybeoutput repeat1 :num-1 :instructions
end

to repeat.done :repeat.result
  if emptyp :repeat.result [op [stop]]
  op list "output quoted first :repeat.result
end

If the instructions do not include STOP or OUTPUT, then REPEAT1 will reach its base case and invoke THROW. As a result, MY.REPEAT’s last instruction line will output an empty list, so the evaluation of the macro result by the caller will do nothing. But if a STOP or OUTPUT happens, then REPEAT.DONE will output a STOP or OUTPUT instruction that will be executed in the caller’s context.

The macro-defining commands have names starting with a dot because macros are an advanced feature of Logo; it’s easy to get in trouble by defining a macro that doesn’t terminate, or by failing to construct the instruction list properly.

Lisp users should note that Logo macros are not special forms. That is, the inputs to the macro are evaluated normally, as they would be for any other Logo procedure. It’s only the output from the macro that’s handled unusually.

Here’s another example:

.macro localmake :name :value
  output (list "local ~
    word "" :name ~
    "apply ~
end
"make

(list :name :value))
end

It's used this way:

to try
  localmake "garply "hello
  print :garply
end

LOCALMAKE outputs the list

[local "garply apply "make [garply hello]]

The reason for the use of APPLY is to avoid having to decide whether or not the second input to MAKE requires a quotation mark before it. (In this case it would — MAKE "GARPLY "HELLO — but the quotation mark would be wrong if the value were a list.)

It's often convenient to use the ' function to construct the instruction list:

.macro localmake :name :value
  op ' [local ,[word "" :name] apply "make [,[:name] ,[:value]]]
end

On the other hand, ' is pretty slow, since it's tree recursive and written in Logo.

See [TO], page 49, [DEFINE], page 50, [APPLY], page 76, [STOP], page 69, [OUTPUT], page 69.

.defmacro
See [dMACRO], page 83.

macrop
MACROP name
MACRO? name
outputs TRUE if its input is the name of a macro.

macroexpand
MACROEXPAND expr (library procedure)
takes as its input a Logo expression that invokes a macro (that is, one that begins with the name of a macro) and outputs the the Logo expression into which the macro would translate the input expression.

.macro localmake :name :value
  op ' [local ,[word "" :name] apply "make [,[:name] ,[:value]]]
end

? show macroexpand [localmake "pi 3.14159]
[local "pi apply "make [pi 3.14159]]
10 Error Processing

If an error occurs, Logo takes the following steps. First, if there is an available variable named ERRACT, Logo takes its value as an instructionlist and runs the instructions. The operation ERROR may be used within the instructions (once) to examine the error condition. If the instructionlist invokes PAUSE, the error message is printed before the pause happens. Certain errors are recoverable; for one of those errors, if the instructionlist outputs a value, that value is used in place of the expression that caused the error. (If ERRACT invokes PAUSE and the user then invokes CONTINUE with an input, that input becomes the output from PAUSE and therefore the output from the ERRACT instructionlist.)

It is possible for an ERRACT instructionlist to produce an inappropriate value or no value where one is needed. As a result, the same error condition could recur forever because of this mechanism. To avoid that danger, if the same error condition occurs twice in a row from an ERRACT instructionlist without user interaction, the message 'Erract loop' is printed and control returns to toplevel. "Without user interaction" means that if ERRACT invokes PAUSE and the user provides an incorrect value, this loop prevention mechanism does not take effect and the user gets to try again.

During the running of the ERRACT instructionlist, ERRACT is locally unbound, so an error in the ERRACT instructions themselves will not cause a loop. In particular, an error during a pause will not cause a pause-within-a-pause unless the user reassigns the value [PAUSE] to ERRACT during the pause. But such an error will not return to toplevel; it will remain within the original pause loop.

If there is no available ERRACT value, Logo handles the error by generating an internal THROW "ERROR. (A user program can also generate an error condition deliberately by invoking THROW.) If this throw is not caught by a CATCH "ERROR in the user program, it is eventually caught either by the toplevel instruction loop or by a pause loop, which prints the error message. An invocation of CATCH "ERROR in a user program locally unbinds ERRACT, so the effect is that whichever of ERRACT and CATCH "ERROR is more local will take precedence.

If a floating point overflow occurs during an arithmetic operation, or a two-input mathematical function (like POWER) is invoked with an illegal combination of inputs, the 'doesn't like' message refers to the second operand, but should be taken as meaning the combination.

See [ERRACT], page 89, [THROW], page 69, [ERROR], page 70, [CATCH], page 69, [PAUSE], page 70, [CONTINUE], page 70.

10.1 Error Codes

Here are the numeric codes that appear as the first member of the list output by ERROR when an error is caught, with the corresponding messages. Some messages may have two different codes depending on whether or not the error is recoverable (that is, a substitute value can be provided through the ERRACT mechanism) in the specific context. Some messages are warnings rather than errors; these will not be caught. Errors 0 and 32 are so bad that Logo exits immediately.

0 Fatal internal error   (can’t be caught)
1 Out of memory
2 Stack overflow
3 Turtle out of bounds
4 proc doesn’t like datum as input (not recoverable)
5 proc didn’t output to proc
6 Not enough inputs to proc
7 proc doesn’t like datum as input (recoverable)
8 Too much inside ()’s
9 You don’t say what to do with datum
10 ')’ not found
11 var has no value
12 Unexpected ’)
13 I don’t know how to proc (recoverable)
14 Can’t find catch tag for throwtag
15 proc is already defined
16 Stopped
17 Already dribbling
18 File system error
19 Assuming you mean IFELSE, not IF (warning only)
20 var shadowed by local in procedure call (warning only)
21 Throw "Error
22 proc is a primitive
23 Can’t use TO inside a procedure
24 I don’t know how to proc (not recoverable)
25 IFTRUE/IFFALSE without TEST
26 Unexpected ’]
27 Unexpected ’}]
28 Couldn’t initialize graphics
29 Macro returned value instead of a list
30 You don’t say what to do with value
31 Can only returned STOP or OUTPUT inside a procedure
32 APPLY doesn’t like badthing as input
33 END inside multi-line instruction
34 Really out of memory (can’t be caught)
35 user-generated error message (THROW "ERROR message)
36 END inside multi-line instruction
37 Bad default expression for optional input: expr
38 Can’t use OUTPUT or STOP inside RUNRESULT
39 Assuming you meant ’FD 100’, not FD100 (or similar)
40 I can’t open file filename
41 File filename already open
42 File filename not open
43 Runlist [expr expr] has more than one expression.
11 Special Variables

Logo takes special action if any of the following variable names exists. They follow the normal scoping rules, so a procedure can locally set one of them to limit the scope of its effect. Initially, no variables exist except for ALLOWGETSET, CASEIGNOREDP, and UNBURYONEDIT, which are TRUE and buried.

allowgetset

ALLOWGETSET (variable)

if TRUE, indicates that an attempt to use a procedure that doesn’t exist should be taken as an implicit getter or setter procedure (setter if the first three letters of the name are SET) for a variable of the same name (without the SET if appropriate).

buttonact

BUTTONACT (variable)

if nonempty, should be an instruction list that will be evaluated whenever a mouse button is pressed. Note that the user may have released the button before the instructions are evaluated. BUTTON will still output which button was most recently pressed. CLICKPOS will output the position of the mouse cursor at the moment the button was pressed; this may be different from MOUSEPOS if the user moves the mouse after clicking.

Note that it’s possible for the user to press a button during the evaluation of the instruction list. If this would confuse your program, prevent it by temporarily setting BUTTONACT to the empty list. One easy way to do that is the following:

make "buttonact [button.action]

to button.action [:buttonact []]
  ... ; whatever you want the button to do
end

caseignoredp

CASEIGNOREDP (variable)

if TRUE, indicates that lower case and upper case letters should be considered equal by EQUALP, BEFOREP, MEMBERP, etc. Logo initially makes this variable TRUE, and buries it.

See [EQUALP], page 14, [BEFOREP], page 15, [MEMBERP], page 15.

commandline

COMMANDLINE (variable)

contains any text appearing after a hyphen on the command line used to start Logo.

erreact

ERRACT (variable)
an instruction list that will be run in the event of an error. Typically has the value [PAUSE] to allow interactive debugging.

See [PAUSE], page 70.

fullprintp

FULLPRINTP (variable)

if TRUE, then words that were created using backslash or vertical bar (to include characters that would otherwise not be treated as part of a word) are printed with the backslashes or vertical bars shown, so that the printed result could be re-read by Logo to produce the same value. If FULLPRINTP is TRUE then the empty word (however it was created) prints as ||. (Otherwise it prints as nothing at all.)

keyact

KEYACT (variable)

if nonempty, should be an instruction list that will be evaluated whenever a key is pressed on the keyboard. The instruction list can use READCHAR to find out what key was pressed. Note that only keys that produce characters qualify; pressing SHIFT or CONTROL alone will not cause KEYACT to be evaluated.

Note that it’s possible for the user to press a key during the evaluation of the instruction list. If this would confuse your program, prevent it by temporarily setting KEYACT to the empty list. One easy way to do that is the following:

```
make "keyact [key.action]

to key.action [:keyact []]
  ... ; whatever you want the key to do
end
```

loadnoisily

LOADNOISILY (variable)

if TRUE, prints the names of procedures defined when loading from a file (including the temporary file made by EDIT).

See [EDIT], page 61.

printdepthlimit

PRINTDEPTHLIMIT (variable)

if a nonnegative integer, indicates the maximum depth of sublist structure that will be printed by PRINT, etc.

See [PRINT], page 19.

printwidthlimit

PRINTWIDTHLIMIT (variable)
if a nonnegative integer, indicates the maximum number of members in any one list that will be printed by PRINT, etc.

See [PRINT], page 19.

**redefp**

REDEF

(variable)

if TRUE, allows primitives to be erased (ERASE) or redefined (COPYDEF).

See [ERASE], page 57, [COPYDEF], page 51.

**startup**

STARTUP

(variable)

if assigned a list value in a file loaded by LOAD, that value is run as an instructionlist after the loading.

See [LOAD], page 63.

**unburyonedit**

UNBURYONEDIT

(variable)

if TRUE, causes any procedure defined during EDIT or LOAD to be unburied, so that it will be saved by a later SAVE. Files that want to define and bury procedures must do it in that order.

See [EDIT], page 61, [LOAD], page 63, See [SAVE], page 62.

**usealternatenames**

USEALTERNATENAMES

(variable)

if TRUE, causes Logo to generate non-English words (from the ‘Messages’ file) instead of TRUE, FALSE, END, etc.

Logo provides the following buried variables that can be used by programs:

**logoversion**

LOGOVERSION

(variable)

a real number indicating the Logo version number, e.g., 5.5

**logoplatform**

LOGOPLATFORM

(variable)

one of the following words: wxWidgets, X11, Windows, or Unix-nographics.
12 Internationalization

Berkeley Logo has limited support for non-English-speaking users. Alas, there is no Unicode support, and high-bit-on ASCII codes work in some contexts but not others.

If you want to translate Berkeley Logo for use with another language, there are three main things you have to do:

1. Primitive names
2. Error (and other) messages
3. Documentation

For primitive names, the easiest thing is to provide a startup file that defines aliases for the English primitive names, using COPYDEF:

    COPYDEF "AVANT "FORWARD

This should take care of it, unless your language's name for one primitive is spelled like the English name of a different primitive. In that case you have to turn REDEFP on and be sure to copy the non-conflicting name before overwriting the conflicting one!

"Primitives" that are actually in the Logo library, of course, can just be replaced or augmented with native-language-named Logo procedures and filenames.

Of course Logo programs will still not look like your native language if the word order is dramatically different, especially if you don’t put verbs before their objects.

For error messages, there is a file named ‘Messages’ in the ‘logolib’ directory with texts of messages, one per line. You can replace this with a file for your own language. Do not add, delete, or reorder lines; Logo finds messages by line number. The sequences %p, %s, and %t in these messages represent variable parts of the message and should not be translated. (%p PRINTs the variable part, while %s SHOWs it – that is, the difference is about whether or not brackets are shown surrounding a list. %t means that the variable part is a C text string rather than a Logo object.) If you want to change the order of two variable parts (no reorderable message has more than two), you would for example replace the line

    %p doesn’t like %s as input

with

    %s is a lousy input to %p

The plus sign tells the message printer to reverse the order; you must reverse the order of %p and %s, if both are used, to match. The plus sign goes just after the first percent sign in the message, which might not be at the beginning of the line. The sequence \n in a message represents a newline; don’t be fooled into thinking that the \n is part of the following word.

Some messages appear twice in the file; this isn’t a mistake. The two spaces before to in I don’t know how \n to aren’t a mistake either. The message containing just %p is for user-provided error messages in THROW "ERROR. The message "\n in %s \n %s" is the part of all error messages that indicates where the error occurred if it was inside a procedure; you might want to change the word in to your language. %s defined \n is what LOAD prints
for each procedure defined if the variable LOADNOISILY is TRUE. "to %p\nend\n\n" is what EDIT puts in the temporary file if you ask to edit a procedure that isn’t already defined.

Also in the ‘Messages’ file are lines containing only one word each; the first of these is the word true. Some of these words are recognized by Logo in user input; some are generated by Logo; some are both. For example, the words TRUE and FALSE are recognized as Boolean values by IF and IFELSE, and are also generated by Logo as outputs from the primitive predicates such as EQUALP. The word END is recognized as the end of a procedure definition, and may be generated when Logo reconstructs a procedure body for PO or EDIT. I’ve used capital letters in this paragraph for easier reading, but the words in the ‘Messages’ file should be in lower case.

If you replace these with non-English words, Logo will recognize both the English names and your alternate names. For example, if you replace the word true with vrai then Logo will understand both of these:

```logo
IF "TRUE [PRINT "YES"
IF "VRAI [PRINT "YES"
```

The variable UseAlternateNames determines whether Logo will generate other-language names – for example, whether predicate functions return the other-language alternates for TRUE and FALSE. This variable is FALSE by default, meaning that the English words will be generated.

You might wish to have English-named predicate functions generate English TRUE and FALSE, while other-language-named predicates generate the alternate words. This can be done by leaving UseAlternateNames false, and instead of defining the other-language predicates with COPYDEF, do it this way:

```logo
to french.boolean :bool
  if equalp :bool "true [output "vrai"
  if equalp :bool "false [output "faux"
  output :bool ; shouldn’t happen
end

to make.french.predicate :french :english :arity
  define :french ‘[[[inputs] ,[:arity]]
     [output french.boolean
       apply ,[word"" :english] :inputs]]
  end

? make.french.predicate "egal? "equal? 2
? pr egal? 3 4
  faux
? pr egal? 4 4
  vrai
? pr equal? 3 4
  false
? pr equal? 4 4
```
true

The third input to `make.french.predicate` is the number of inputs that the predicate expects. This solution isn’t quite perfect because the infix predicates (=, <, >) will still output in English. If you want them to generate alternate-language words, set `UseAlternateNames` to `TRUE` instead.

Some of the words in this section of the ‘Messages’ file are names of Logo primitives (`OUTPUT, STOP, GOTO, TAG, IF, IFELSE, TO, .MACRO`). To translate these names, you must use `COPYDEF` as described earlier, in addition to changing the names in ‘Messages’. You should be consistent in these two steps. Don’t forget the period in `.macro`!

For documentation, there are two kinds: this manual and the help files. The latter are generated automatically from this manual if you have a Unix system, so in that case you need only translate this manual, maintaining the format. (The automatic helpfile generator notices things like capital letters, tabs, hyphens, and equal signs at the beginnings of lines.) The program `makefile.c` may require modification because a few of the primitive names are special cases (e.g., `LOG10` is the only name with digits included).

If you don’t have Unix tools, you can just translate each helpfile individually. A period in a primitive name is represented as a `D` in the filename; there are no files for question marks because the `HELP` command looks for the file named after the corresponding primitive that ends in `P`.
