

Math 55 - Spring 2004 - Lecture notes # 9 - Feb 19 (Thursday)

Finish through end of Section 2.6 (not 2.7) if not yet done
Start reading Sections 3.1 - 3.4

Homework, due Feb 25

- (1) Let $a = a_4a_3a_2a_1a_0$ be a 5-bit 2s complement integer; each a_i is 0 or 1. Similarly let $b = b_4b_3b_2b_1b_0$, and let $s = a+b = s_4s_3s_2s_1s_0$ be their sum in 2s complement arithmetic.
- Interpreting a 0 bit as False and a 1 bit as True, write down logical formulas for s_4, s_3, s_2, s_1, s_0 using and, or, not, xor, with the inputs $a_4, a_3, a_2, a_1, a_0, b_4, b_3, b_2, b_1, b_0$.
- Hint: introduce new logical variables (bits) c_4, c_3, c_2, c_1, c_0 where c_i is the carry into the i -th bit from the $i-1$ -st bit. Your logical formulas for s_i and c_{i+1} in terms of a_i, b_i and c_i should look the same for all i (you can let $c_0 = 0 = \text{False}$ so that all the formulas look the same).
- In particular, your formulas should express the facts that $c_{i+1}=1$ if the sum $a_i + b_i + c_i$ is at least 2, and $s_i = 1$ if $a_i + b_i + c_i$ is 1 or 3 (i.e. odd).
- Computers implement these formulas in hardware to perform 2s complement addition.
- (2) Explain how to use nearly the same logical formulas as above to compute the difference $d = a-b$
- (3) The purpose of this question is to illustrate that there are a lot of primes.
- (a) Let n and d be integers, and $x = n \cdot 10^d$
- Use the prime number theorem to evaluate the limit as $d \rightarrow \infty$ of $\pi(x + 10^d) / \pi(x)$ where $\pi(x)$ is the number of primes less than or equal to x . (in other words, n is fixed and d is growing)
- (b) Use part(a) to show that given any arbitrary string of decimal digits (representing the integer n), then for all sufficiently large M , there is always a prime p such that
1. p has an M -digit decimal expansion, and
 2. p 's decimal expansion starts with the given string (representing n).

2.6-20,24

Goals for today: Recall Euclidean algorithm for the gcd
Use it to solve a "congruence equation"
 $a*x=b \pmod m$ for x
how to do division in modular arithmetic
Use it to solve a system of congruence equations:
Chinese Remainder Theorem
Apply it to cyptography

Recall property of Euclidean algorithm for gcd: given a and m ,
it computes

- 1) $d = \gcd(a,m)$
- 2) integers s and t such that $a*s+m*t=d$

How to solve $a*x \equiv 1 \pmod m$ for x :

(analogy of reciprocal of a in modular arithmetic)

Theorem: $a*x \equiv 1 \pmod m$ can be solved for x if and only if $\gcd(a,m)=1$.

When it can be solved, x is unique mod m , i.e. the only one in
the range 0 to $m-1$, and is called "the inverse of a modulo m ".

EX: Solve $2*x \equiv 1 \pmod 5$: try $x=0,1,2,3,4$,
getting $2*x=0,2,4,1,3$,
so $x=3$ is the unique answer ($\gcd(2,5)=1$)

EX: Solve $2*x \equiv 1 \pmod 4$: try $x=0,1,2,3$,
getting $2*x=0,2,0,2$,
so there is no solution ($\gcd(2,4)=2$)

Proof: If $\gcd(a,m)=1$, we have to show that we can solve for x :
Use the Euclidean algorithm to find s and t such that
 $a*s+m*t=1$. Thus $a*s = 1-m*t \equiv 1 \pmod m$, so $x=s$ is a solution.

If $\gcd(a,m) \neq 1$, we have to show that no x satisfies
 $a*x \equiv 1 \pmod m$: Recall that $a*x \equiv 1 \pmod m$ is equivalent to
 $a*x \pmod m = 1 \pmod m = 1$, and that $a*x \pmod m = a*x+m*t$
for some t . But if $\gcd(a,m)=d>1$, then $d|a$ and $d|m$,
so $d|(a*x+m*t)$ for any integer t , and in particular
 $d|(a*x \pmod m)$. Since d does not divide 1 , $a*x \pmod m \neq 1$.

To show that the solution x is unique mod m when it exists,
suppose both that $a*x_1 \equiv 1 \pmod m$ and $a*x_2 \equiv 1 \pmod m$, and
that $1 \leq x_1 < m$ and $1 \leq x_2 < m$; we have to show that $x_1=x_2$.
Now $a*x_1-a*x_2 \equiv 0 \pmod m$, so $m|(a*(x_1-x_2))$.
Since $\gcd(a,m)=1$, a and m have no common factors,

and thus $m|(x_1-x_2)$. Now x_1-x_2 satisfies two properties:

1) $m|(x_1-x_2)$, so x_1-x_2 is in the set

$\{\dots, -2*m, -m, 0, m, 2*m, \dots\}$

2) $-m < x_1-x_2 < m$, since $1 \leq x_1 < m$ and $1 \leq x_2 < m$;

The only value of x_1-x_2 satisfying these properties is $x_1-x_2=0$, or $x_1=x_2$ as desired.

Corollary: $a*y \equiv b \pmod m$ has a solution y for any b if and only if $\gcd(a,m) \equiv 1$ (analogy of dividing b/a in modular arithmetic)

proof: if $\gcd(a,m)=1$, then the Theorem says we can solve

$a*x \equiv 1 \pmod m$. Multiply through by b to get

$a*(x*b) \equiv b \pmod m$, so we can take $y = x*b$

(b times "inverse of a ") If $\gcd(a,m) > 1$,

then the Theorem tells us we cannot solve when $b \neq 1$.

ASK&WAIT: under what conditions on b can we solve $a*y \equiv b \pmod m$ for y ?

Chinese Remainder Theorem: Let m_1, m_2, \dots, m_n be pairwise

relatively prime numbers, ie $\gcd(m_i, m_j) = 1$ for all i and j .

Let $M = m_1*m_2*\dots*m_n$. Then the n equations

$x \equiv a_1 \pmod{m_1}$, $x \equiv a_2 \pmod{m_2}$, \dots , $x \equiv a_n \pmod{m_n}$

have a unique solution mod M for any a_1, a_2, \dots, a_n , i.e. there is only one solution in the range from 0 to $M-1$.

EX: $x \equiv 2 \pmod 3$, $x \equiv 3 \pmod 5$

x	$x \equiv 2 \pmod 3$?	$x \equiv 3 \pmod 5$?
0		
1		
2	Yes	
3		Yes
4		
5	Yes	
6		
7		
8	Yes	Yes
9		
10		
11	Yes	
12		
13		Yes
14	Yes	

Proof: We give an algorithm for computing x , and leave uniqueness to

homework. Let $M_i = m/m_i$, for $i=1, \dots, n$. Thus
 $M_i =$ product of all m_j except for m_i , so $\gcd(M_i, m_i)=1$, since
 m_j and m_i have no common factors. By the last theorem, each
 M_i has an inverse $y_i \pmod{m_i}$, i.e. $M_i y_i \equiv 1 \pmod{m_i}$.
We claim a solution is $x = a_1 M_1 y_1 + a_2 M_2 y_2 + \dots + a_n M_n y_n$.
To confirm this we have to verify that $x \equiv a_i \pmod{m_i}$ for all i :

$$\begin{aligned} x &\equiv (a_1 M_1 y_1 + a_2 M_2 y_2 + \dots + a_n M_n y_n) \pmod{m_i} \\ &\equiv (a_1 M_1 y_1 \pmod{m_i} + \dots + a_n M_n y_n \pmod{m_i}) \pmod{m_i} \\ &\equiv (a_i M_i y_i \pmod{m_i} \\ &\quad + \sum_{j \neq i} a_j M_j y_j) \pmod{m_i} \\ &\equiv a_i \pmod{m_i} \quad \text{since } M_i y_i \equiv 1 \pmod{m_i} \\ &\quad + 0 \quad \text{since } m_i \mid M_j \text{ when } j \neq i \\ &\equiv a_i \pmod{m_i} \quad \text{as desired} \end{aligned}$$

EX: $x \equiv 2 \pmod{3}$, $x \equiv 3 \pmod{5}$ again:
 $a_1=2$, $m_1=3$, $a_2=3$, $m_2=5$, $M_1=5$, $M_2=3$,
 $y_1=2$ since $2 \cdot 5 \equiv 1 \pmod{3}$ and $y_2=2$ since $2 \cdot 3 \equiv 1 \pmod{5}$
 $x = 2 \cdot 5 \cdot 2 + 3 \cdot 3 \cdot 2 = 38 \equiv 8 \pmod{15}$

Cryptography

Recall that a message (character string) is converted to a number M
What happens when a Sender wants to send a secret message to
a Receiver:

The Sender takes message M and encrypts it to get the
encrypted message $C = f_{\text{enc}}(M)$

The Sender sends C to the Receiver. Anyone may "intercept"
 C on its way.

The Receiver decrypts C to get the original message $M = f_{\text{dec}}(C)$.

For this to work as the Sender and Receiver desire:

f_{enc} and f_{dec} have to be one-to-one, onto functions and be
inverses of one another, i.e. $M = f_{\text{dec}}(f_{\text{enc}}(M))$ for all M

It is easy for the Sender to evaluate f_{enc}

It is easy for the Receiver to evaluate f_{dec}

It is very hard for anyone other than the Receiver to evaluate
 f_{dec} . The harder it is, the better the secrecy.

Two kinds of cryptography:

Private key (traditional): need one "Key" for both f_{enc} and f_{dec}
where $K=$ Key is a shared secret between Sender, Receiver

EX: shift: $C = f_{\text{enc}}(M) = M-K \pmod{n}$, $M = f_{\text{dec}}(C) = C+K \pmod{n}$,

easy to break

ASK&WAIT: How?

EX: xor: $C = f_{\text{enc}}(M) = M \text{ xor } K$ (thinking of M, C, K as bit strings of the same length)

$M = f_{\text{dec}}(C) = C \text{ xor } K$

ASK&WAIT: Why are f_{enc} and f_{dec} inverses?

hard to break if K used once

EX: Original Washington/Moscow hotline worked this way

EX: crypt command in UNIX, uses algorithm from German Enigma machine used in World War II, which was broken by Turing

Secrecy depends on keeping K a secret known only to Sender, Receiver so only they can evaluate f_{enc} and f_{dec}

Disadvantage: if 1000 people want to talk to one another in secret, need 999×1000 secret keys, so all pairs can talk; too many keys!

Public key: any Sender can do f_{enc} , but only one Receiver can do f_{dec}

Advantage: for 1000 people to talk in secret, each person has his/her own secret f_{dec} , but can just publish the corresponding f_{enc}

EX: RSA (Rivest/Shamir/Adleman)

Need: 1) large number n that is product of two large primes $p \times q = n$
large means 200 to 400 decimal digits

2) integer e that is relatively prime to $(p-1) \times (q-1)$

3) integer $d = \text{inverse of } e \text{ mod } (p-1) \times (q-1)$

Everyone knows n and e , but only Receiver knows d

Then for message M , $C = f_{\text{enc}}(M) = M^e \text{ mod } n$ is the encrypted message

For encrypted message C , $M = f_{\text{dec}}(C) = C^d \text{ mod } n$ is the decrypted message

EX: Try $2537 = n = p \times q = 43 \times 59$, $e = 13$, message = STOP = (ST,OP) = (1819,1415)
using position of letters in alphabet. Then encrypted message
= ($1819^{13} \text{ mod } 2537$, $1415^{13} \text{ mod } 2537$) = (2081, 2182).

To decrypt we use $d = 937$ and compute

($2081^{937} \text{ mod } 2537$, $2182^{937} \text{ mod } 2537$) = (1819,1415)

We will show that f_{enc} and f_{dec} are inverses of one another shortly.

But first, why is $f_{\text{enc}}()$ easy and $f_{\text{dec}}()$ hard to evaluate?

$f_{\text{enc}}()$ requires multiplying by M and taking the remainder mod n , both of which are easy, even if M and n are large.

$f_{\text{dec}}()$ equally easy if we know d , which only the Receiver knows.

Why is it hard to figure out d ? All you have to do is

1) factor $n = p \times q$

2) use Euclidean algorithm to compute d so $d \times e \equiv 1 \text{ mod } (p-1) \times (q-1)$

But 1) is very hard: Best algorithms would take billions of years if n has 400 digits. And any other known algorithm to compute d leads to computing p and q too. So quality of encryption depends on large integers being very hard to factor. If you figure out an algorithm to factor quickly, you can become rich or famous.

Proof that $f_dec()$ is inverse of f_enc requires Fermat's Little Theorem (proof is questions 15-17 in section 2.6):

If p is prime and $p \nmid a$, then $a^{(p-1)} \equiv 1 \pmod p$

Proof that $f_dec(f_enc(M)) = M$, where $M < p, q$

$f_dec(f_enc(M)) = f_dec(M^e \pmod n) = (M^e)^d \pmod n = M^{(e*d)} \pmod n$.

We need to show that $M^{(e*d)} \pmod n = M \pmod n = M$, since $M < p*q = n$.

Now $e*d \equiv 1 \pmod{(p-1)*(q-1)}$ so $e*d = 1 + m*(p-1)*(q-1)$ for some m . Then

$$\begin{aligned} M^{(e*d)} \pmod n &= M^{(1 + m*(p-1)*(q-1))} \pmod n \\ &= M * M^{(m*(p-1)*(q-1))} \pmod n \end{aligned}$$

Now since $M < p$ and $M < q$, and p and q are prime, we must have $\gcd(M, p) = \gcd(M, q) = 1$. Then Fermat's Little Theorem implies that $M^{(p-1)} \equiv 1 \pmod p$ and $M^{(q-1)} \equiv 1 \pmod q$.

$$\begin{aligned} \text{Thus } M^{(e*d)} &= M * (M^{(p-1)})^{(m*(q-1))} \\ &\equiv M * (1)^{(m*(q-1))} \pmod p \\ &\equiv M \pmod p \end{aligned}$$

$$\begin{aligned} \text{and } M^{(e*d)} &= M * (M^{(q-1)})^{(m*(p-1))} \\ &\equiv M * (1)^{(m*(p-1))} \pmod q \\ &\equiv M \pmod q. \end{aligned}$$

Finally, by the Chinese Remainder Theorem, $M^{(e*d)}$ is the unique solution mod $p*q$ to

$$x \equiv M \pmod p$$

$$x \equiv M \pmod q$$

so $M^{(e*d)} \pmod n = M$ as desired.

For RSA to be useful, we need to find a lot of large primes. We will not discuss the algorithm for finding them, but just discuss the theorem that says there are a lot to be found:

Def: $\pi(n)$ = the number of primes $\leq n$

Ex: $\pi(20) = |\{2,3,5,7,11,13,17,19\}| = 8$

Theorem (Prime Number Theorem): The limit as $n \rightarrow$ infinity of $\pi(n) / (n / \log_e n) = 1$

EX:	n	$\pi(n)$	$n/\log_e(n)$	$\pi(n) / (n/\log_e n)$
	10^1	4	4.3	.92

10 ²	25	21.7	1.15
10 ³	168	144.8	1.16
10 ⁴	1229	1085.7	1.13
10 ⁵	9592	8685.9	1.10
10 ⁶	78498	72382.4	1.08
10 ⁷	664579	620420.7	1.07
10 ⁸	5761455	5428681.0	1.06

The point is that the ratio in the last column is slowly approaching 1

So about what fraction of 200 decimal digit numbers are prime?

$$\begin{aligned}
 & \# \text{ 200 digit primes} / \# \text{ 200 digit numbers} \\
 = & \left(\text{pi}(10^{200}) - \text{pi}(10^{199}) \right) / \left(10^{200} - 10^{199} \right) \\
 \sim & \left(10^{200}/\log_e(10^{200}) - 10^{199}/\log_e(10^{199}) \right) / \left(10^{200} - 10^{199} \right) \\
 \sim & .002 \text{ or about 1 out of 500}
 \end{aligned}$$

So if you pick 500 random 200 digit numbers,
there is a reasonable chance that one is prime
