

Statistical NLP Spring 2010

Lecture 12: Parsing I

Dan Klein – UC Berkeley

Parse Trees

The move followed a round of similar increases by other lenders, reflecting a continuing decline in that market

Phrase Structure Parsing

- Phrase structure parsing organizes syntax into *constituents* or *brackets*

- In general, this involves nested trees
- Linguists can, and do, argue about details
- Lots of ambiguity
- Not the only kind of syntax...

new art critics write reviews with computers

Constituency Tests

- How do we know what nodes go in the tree?

- Classic constituency tests:

- Substitution by *proform*
- Question answers
- Semantic grounds
 - Coherence
 - Reference
 - Idioms
- Dislocation
- Conjunction

- Cross-linguistic arguments, too

Conflicting Tests

- Constituency isn't always clear

- Units of transfer:
 - think about ~ penser à
 - talk about ~ hablar de

- Phonological reduction:
 - I will go → I'll go
 - I want to go → I wanna go
 - a le centre → au centre

- Coordination
 - He went to and came from the store.

Classical NLP: Parsing

- Write symbolic or logical rules:

Grammar (CFG)	Lexicon
ROOT → S	NN → interest
S → NP VP	NNS → raises
NP → DT NN	VBP → interest
NP → NN NNS	VBZ → raises
VP → VB NP	...
VP → VBP NP PP	
PP → IN NP	

- Use deduction systems to prove parses from words

- Minimal grammar on "Fed raises" sentence: 36 parses
- Simple 10-rule grammar: 592 parses
- Real-size grammar: many millions of parses

- This scaled very badly, didn't yield broad-coverage tools

Ambiguities: PP Attachment

Attachments

- I cleaned the dishes from dinner
- I cleaned the dishes with detergent
- I cleaned the dishes in my pajamas
- I cleaned the dishes in the sink

Syntactic Ambiguities I

- **Prepositional phrases:**
They cooked the beans in the pot on the stove with handles.
- **Particle vs. preposition:**
The puppy tore up the staircase.
- **Complement structures**
The tourists objected to the guide that they couldn't hear.
She knows you like the back of her hand.
- **Gerund vs. participial adjective**
Visiting relatives can be boring.
Changing schedules frequently confused passengers.

Syntactic Ambiguities II

- **Modifier scope within NPs**
impractical design requirements
plastic cup holder
- **Multiple gap constructions**
The chicken is ready to eat.
The contractors are rich enough to sue.
- **Coordination scope:**
Small rats and mice can squeeze into holes or cracks in the wall.

Probabilistic Context-Free Grammars

- A context-free grammar is a tuple $\langle N, T, S, R \rangle$
 - N : the set of non-terminals
 - Phrasal categories: S, NP, VP, ADJP, etc.
 - Parts-of-speech (pre-terminals): NN, JJ, DT, VB
 - T : the set of terminals (the words)
 - S : the start symbol
 - Often written as ROOT or TOP
 - Not usually the sentence non-terminal S
 - R : the set of rules
 - Of the form $X \rightarrow Y_1 Y_2 \dots Y_k$, with $X, Y_i \in N$
 - Examples: $S \rightarrow NP VP$, $VP \rightarrow VP CC VP$
 - Also called rewrites, productions, or local trees
- A PCFG adds:
 - A top-down production probability per rule $P(Y_1 Y_2 \dots Y_k | X)$

Trebank Sentences

```
( (S (NP-SBJ The move)
  (VP followed
    (NP (NP a round)
      (PP of
        (NP (NP similar increases)
          (PP by
            (NP other lenders))
          (PP against
            (NP Arizona real estate loans))))))
    (S-ADV (NP-SBJ *)
      (VP reflecting
        (NP (NP a continuing decline)
          (PP-LOC in
            (NP that market))))))
  .))
```

Treebank Grammars

- Need a PCFG for broad coverage parsing.
- Can take a grammar right off the trees (doesn't work well):

- Better results by enriching the grammar (e.g., lexicalization).
- Can also get reasonable parsers without lexicalization.

Treebank Grammar Scale

- Treebank grammars can be enormous
 - As FSAs, the raw grammar has ~10K states, excluding the lexicon
 - Better parsers usually make the grammars larger, not smaller

Chomsky Normal Form

- Chomsky normal form:
 - All rules of the form $X \rightarrow YZ$ or $X \rightarrow w$
 - In principle, this is no limitation on the space of (P)CFGs
 - N-ary rules introduce new non-terminals

- Unaries / empties are "promoted"
- In practice it's kind of a pain:
 - Reconstructing n-aries is easy
 - Reconstructing unaries is trickier
 - The straightforward transformations don't preserve tree scores
- Makes parsing algorithms simpler!

A Recursive Parser

```

bestScore(X, i, j, s)
  if (j = i+1)
    return tagScore(X, s[i])
  else
    return max score(X->YZ) *
              bestScore(Y, i, k) *
              bestScore(Z, k, j)
    
```

- Will this parser work?
- Why or why not?
- Memory requirements?

A Memoized Parser

- One small change:

```

bestScore(X, i, j, s)
  if (scores[X][i][j] == null)
    if (j = i+1)
      score = tagScore(X, s[i])
    else
      score = max score(X->YZ) *
                bestScore(Y, i, k) *
                bestScore(Z, k, j)
    scores[X][i][j] = score
  return scores[X][i][j]
    
```

A Bottom-Up Parser (CKY)

- Can also organize things bottom-up

```

bestScore(s)
  for (i : [0, n-1])
    for (X : tags[s[i]])
      score[X][i][i+1] =
        tagScore(X, s[i])
  for (diff : [2, n])
    for (i : [0, n-diff])
      j = i + diff
      for (X->YZ : rule)
        for (k : [i+1, j-1])
          score[X][i][j] = max score[X][i][j],
                              score(X->YZ) *
                              score[Y][i][k] *
                              score[Z][k][j]
    
```

Unary Rules

- Unary rules?

```

bestScore(X,i,j,s)
  if (j = i+1)
    return tagScore(X,s[i])
  else
    return max max score(X->YZ) *
               bestScore(Y,i,k) *
               bestScore(Z,k,j)
               max score(X->Y) *
               bestScore(Y,i,j)
    
```

CNF + Unary Closure

- We need unaries to be non-cyclic
 - Can address by pre-calculating the *unary closure*
 - Rather than having zero or more unaries, always have exactly one

- Alternate unary and binary layers
- Reconstruct unary chains afterwards

Alternating Layers

```

bestScoreB(X,i,j,s)
  return max max score(X->YZ) *
             bestScoreU(Y,i,k) *
             bestScoreU(Z,k,j)

bestScoreU(X,i,j,s)
  if (j = i+1)
    return tagScore(X,s[i])
  else
    return max max score(X->Y) *
             bestScoreB(Y,i,j)
    
```

Memory

- How much memory does this require?
 - Have to store the score cache
 - Cache size: |symbols|² doubles
 - For the plain treebank grammar:
 - X ~ 20K, n = 40, double ~ 8 bytes = ~ 256MB
 - Big, but workable.
- Pruning: Beams
 - score[X][i][j] can get too large (when?)
 - Can keep beams (truncated maps score[i][j]) which only store the best few scores for the span [i,j]
- Pruning: Coarse-to-Fine
 - Use a smaller grammar to rule out most X[i,j]
 - Much more on this later...

Time: Theory

- How much time will it take to parse?

- For each diff ($\leq n$)
 - For each i ($\leq n$)
 - For each rule $X \rightarrow YZ$
 - For each split point k
 - Do constant work

- Total time: |rules|*n³
- Something like 5 sec for an unoptimized parse of a 20-word sentences

Time: Practice

- Parsing with the vanilla treebank grammar:

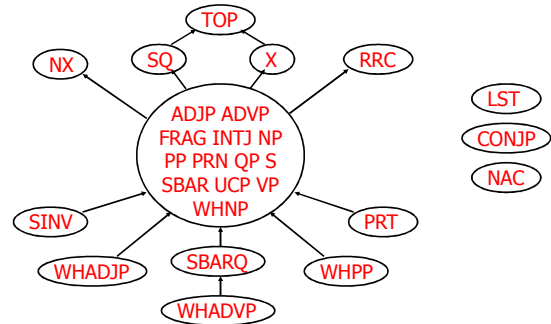

~ 20K Rules
(not an optimized parser!)
Observed exponent:
3.6

- Why's it worse in practice?
 - Longer sentences "unlock" more of the grammar
 - All kinds of systems issues don't scale

Efficient CKY

- Lots of tricks to make CKY efficient
 - Most of them are little engineering details:
 - E.g., first choose k , then enumerate through the $Y:[i,k]$ which are non-zero, then loop through rules by left child.
 - Optimal layout of the dynamic program depends on grammar, input, even system details.
 - Another kind is more critical:
 - Many $X:[i,j]$ can be suppressed on the basis of the input string
 - We'll see this next class as figures-of-merit or A^* heuristics

Same-Span Reachability

Rule State Reachability

Example: NP CC •

Example: NP CC NP •

- Many states are more likely to match larger spans!

Unaries in Grammars
