Introduction: Parallel imaging (PI) [1,2] is a well-established acceleration technique based on the spatial sensitivity of array receivers. Compressed sensing (CS) [3-5] is an emerging acceleration technique that is based on the compressibility of medical images. Attempts to combine [8-13] the two have been limited to straightforward extensions of SENSE [2] with SparseMRI [5]. Here we present a detailed approach on synergistically combining auto-calibrating parallel imaging (acPI) [6,7] with CS. The acquisition and the reconstruction are carefully optimized to fit with the requirements of both methods to achieve highly accelerated robust reconstructions.

Theory: A successful CS reconstruction requires (i) sparsity of representation, (ii) incoherent sampling, and (iii) non-linear sparsity enforcing reconstruction. Here, we reconsider these requirements in the context of acPI and propose: a modified sparsity model for multiple coil images, an incoherent sampling scheme that does not harm the conditioning of acPI reconstruction, and an acPI reconstruction scheme that uses both the coil and the sparsity information.

Methods: I. Joint sparsity of phased array images: The sparse transforms (here, wavelet) of the individual coil images are correlated; therefore we propose a joint sparsity functional [14] that takes the correlation into account. The usual definition of the L$_1$ norm with a single coil is $\Sigma_r|w(r)|$, or the sum of absolute values of all transform coefficients. We define the vector $w(r)=[w_1(r),...,w_n(r)]^T$ to be the coefficients at position r across all n coils, and generalized the L$_1$ norm to be the sum of magnitudes $\Sigma_r\|w(r)\|_2$. **II. Incoherent sampling**: Random sampling provides the high degree of incoherence needed for compressed sensing. However, it is not optimized for parallel imaging. Large gaps between samples that often occur reduce the reconstruction conditioning and increase noise. Sampling according to a (gridded) Poisson-disc distribution [15,16] provides high degree of incoherence and at the same time uniform distance between samples (See Figs. 1 and 2). It also provides flexibility for fractional and anisotropic acceleration (using ellipsoids rather than discs), resulting in better fit to different coil array geometries (See Fig. 2). **III. Reconstruction**: We use an iterative GRAPPA-like approach that is described in detail in [7,17], which we refer to as SPIR-iT (iterative Self-consistent Parallel Imaging Reconstruction). It enforces self-consistency with the calibration and data acquisition and in addition, sparsity of the reconstruction. We minimize the following constrained functional: minimize $\Sigma_r\|w(r)\|_2$ subject to: $Gx=x$, $x|_{acq}=y$, $w=\Psi F^{-1}x$, where x are the desired k-space data, y are acquired k-space, F is a Fourier transform operator, Ψ is a sparse transform (wavelet), w are sparse transform coefficients, and G is a GRAPPA-like convolution operator similarly to [7,17] that is obtained by calibration.
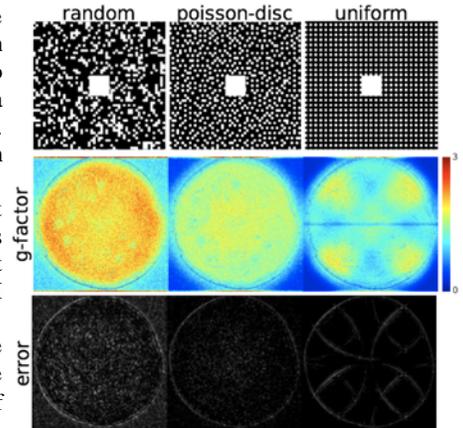

For simplicity, in this work the reconstruction is implemented as a projection over convex sets (POCS) algorithm. (i) Set $x_0=0$ (ii) Apply $x_{i+1}'=Gx_i$ (iii) Set $x_{i+1}'|_{acq}=y$ (iv) compute $w=\Psi F^{-1}x_{i+1}'$ (v) set $w(r)=SoftThresh(\|w\|_2,\lambda)$ (vi) compute $x_{i+1}=F\Psi^{-1}w$ (vii) Set $x_{i+1}|_{acq}=y$ (viii) repeat till convergence. The soft-threshold operation is equivalent to L$_1$ penalty [18] and is defined as: $SoftThresh(w,\lambda) = w/\|w\| \bullet \{\|w\|_2-\lambda\}_+$. Alternatively, more advance reconstructions (nl-Conjugate-gradient, Interior-point, etc.) can be applied.

Results: A patient with cancer lesions in the lower extremities was scanned after admission of a contrast agent using a fat suppressed 3D SPGR sequence on a 1.5T GE Signa Excite scanner. The following parameters were used: TR/TE xxx, res=xxx, FOV=xxx, flip=xxx, acPI calibration=24x24 samples, coil array=4, sampling: Poisson-disc phase encodes, 2D acceleration=5 (x2.5x2). The data was reconstructed with ARC (GE's acPI product reconstruction), CS-wavelet without parallel imaging (Matlab code) and L$_1$-wavelet SPIR-iT (Matlab code). The result in Fig. 3 shows the superior reconstruction of SPIR-iT.

Conclusions: We presented a method to combine CS and acPI. We optimized the sampling and the reconstruction such that the two techniques add synergistically. We demonstrated good robust diagnostic quality reconstruction at acceleration beyond the number of coils.

Figure 1: *g-factor and error maps obtained from a 100 scans. Top: Poisson-disc sampling is both incoherent and uniformly distributed in k-space. Middle (in color): The noise amplification in Poisson-disc sampling is significantly smaller than random and of the order of uniform sampling. Bottom: The residual error in Poisson-disc sampling is incoherent as opposed to coherent residual in uniform sampling*
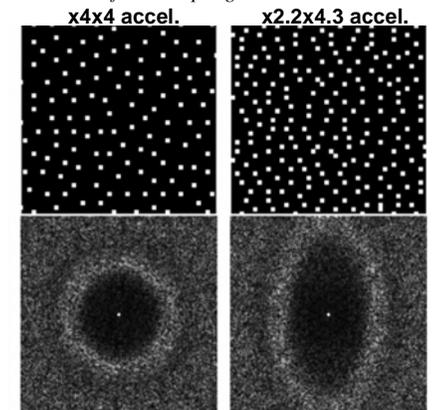

Figure 2: *An example of a 4x4 and a 2.2x4.3 2D accelerated Poisson disc sampling patterns and their associated point spread functions. The incoherent aliasing appears beyond the Nyquist-rate supported field of view. Non-isotropic FOV can be used to adapt to coil array geometries.*

Figure 3: *5-fold (x2.5x2), 4-coils, 2D Poisson-disc accelerated, post contrast lower extremity axial and coronal slices showing enhanced lesions and vessels. Left: ARC reconstruction (GE's acPI product) showing significant (incoherent) noise artifacts. Middle: CS reconstruction showing reduced artifacts, but loss of contrast, loss of subtle feature and some loss of resolution. Right: L$_1$ SPIR-iT reconstruction shows reduced noise artifacts with better depiction of subtle features and resolution.*
