

CS 287: Advanced Robotics Fall 2009

Lecture 11: Reinforcement Learning

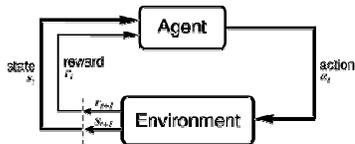

Pieter Abbeel
UC Berkeley EECS

Canonical Example: Grid World

- The agent lives in a grid
- Walls block the agent's path
- The agent's actions do not always go as planned:
 - 80% of the time, the action North takes the agent North (if there is no wall there)
 - 10% of the time, North takes the agent West; 10% East
 - If there is a wall in the direction the agent would have been taken, the agent stays put
- Big rewards come at the end

Reinforcement Learning

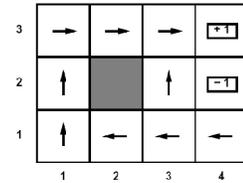

- Model: Markov decision process (S, A, T, R, γ)
 - Goal: Find π that maximizes expected sum of rewards
- T and R might be unknown

[Drawing from Sutton and Barto, Reinforcement Learning: An Introduction, 1998]

Solving MDPs

- In deterministic single-agent search problem, want an optimal **plan**, or sequence of actions, from start to a goal
- In an MDP, we want an optimal **policy** $\pi^*: S \rightarrow A$
 - A policy π gives an action for each state
 - An optimal policy maximizes expected utility if followed
 - Defines a reflex agent

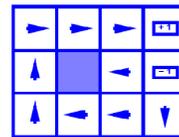

Examples

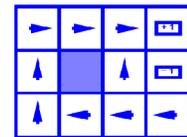

MDP (S, A, T, γ , R), goal: $\max_{\pi} E[\sum_t \gamma^t R(s_t, a_t) | \pi]$

- Cleaning robot
- Walking robot
- Pole balancing
- Games: tetris, backgammon
- Server management
- Shortest path problems
- Model for animals, people

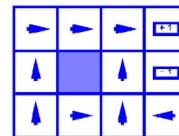

Example Optimal Policies

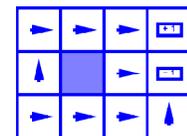

$R(s) = -0.02$

$R(s) = -0.04$

$R(s) = -0.1$

$R(s) = -2.0$

Outline current and next few lectures

- Recap and extend exact methods
 - Value iteration
 - Policy iteration
 - Generalized policy iteration
 - Linear programming [later]
- Additional challenges we will address by building on top of the above:
 - Unknown transition model and reward function
 - Very large state spaces

Example: Value Iteration

	V_2				V_3			
3	0	0	0.72	1	0	0.52	0.78	1
2	0	0	0	-1	0	0	0.43	-1
1	0	0	0	0	0	0	0	0
	1	2	3	4	1	2	3	4

- Information propagates outward from terminal states and eventually all states have correct value estimates

Value Iteration

- Algorithm:
 - Start with $V_0(s) = 0$ for all s .
 - Given V_i , calculate the values for all states for depth $i+1$:

$$V_{i+1}(s) \leftarrow \max_a \sum_{s'} T(s, a, s') [R(s, a, s') + \gamma V_i(s')]$$
 - This is called a **value update** or **Bellman update/back-up**
 - Repeat until convergence

Convergence

Infinity norm: $\|V\|_\infty = \max_s |V(s)|$

Fact. Value iteration converges to the optimal value function V^* which satisfies the Bellman equation:

$$\forall s \in S: V^*(s) = \max_a \sum_{s'} T(s, a, s') (R(s, a, s') + \gamma V^*(s'))$$

Or in operator notation: $V^* = TV^*$ where T denotes the Bellman operator.

Fact. If an estimate V satisfies $\|V - TV\|_\infty \leq \epsilon$ then we have that

$$\|V - V^*\|_\infty \leq \frac{\epsilon}{1 - \gamma}$$

Example: Bellman Updates

3	0	0	0.72	1	0	0	0.72	1
2	0	0	0	-1	0	0	0	-1
1	0	0	0	0	0	0	0	0
	1	2	3	4	1	2	3	4

$$V_{i+1}(s) = \max_a \sum_{s'} T(s, a, s') [R(s, a, s') + \gamma V_i(s')]$$

$$V_2((3,3)) = \sum_{s'} T((3,3), \text{right}, s') [R((3,3), \text{right}, s') + 0.9 V_1(s')] \\ = 0.9 [0.8 \cdot 1 + 0.1 \cdot 0 + 0.1 \cdot 0]$$

Practice: Computing Actions

- Which action should we choose from state s :
 - Given optimal values V^* ?

$$\pi(s) = \arg \max_a \sum_{s'} T(s, a, s') [R(s, a, s') + \gamma V^*(s')]$$

- $\pi(s)$ = greedy action with respect to V^*
- $\pi(s)$ = action choice with one step lookahead w.r.t. V^*

Policy Iteration

- Alternative approach:
 - **Step 1: Policy evaluation:** calculate value function for a fixed policy (not optimal!) until convergence
 - **Step 2: Policy improvement:** update policy using one-step lookahead with resulting converged (but not optimal!) value function
 - Repeat steps until policy converges
- This is **policy iteration**
 - It's still optimal!
 - Can converge faster under some conditions

13

Policy Iteration

- Policy evaluation: with fixed current policy π , find values with simplified Bellman updates:
 - Iterate until values converge

$$V_{i+1}^{\pi_k}(s) \leftarrow \sum_{s'} T(s, \pi_k(s), s') [R(s, \pi_k(s), s') + \gamma V_i^{\pi_k}(s')]$$

- Policy improvement: with fixed utilities, find the best action according to one-step look-ahead

$$\pi_{k+1}(s) = \arg \max_a \sum_{s'} T(s, a, s') [R(s, a, s') + \gamma V^{\pi_k}(s')]$$

14

Comparison

- Value iteration:
 - Every pass (or "backup") updates both utilities (explicitly, based on current utilities) and policy (possibly implicitly, based on current policy)
- Policy iteration:
 - Several passes to update utilities with frozen policy
 - Occasional passes to update policies
- Generalized policy iteration:
 - General idea of two interacting processes revolving around an approximate policy and an approximate value
- Asynchronous versions:
 - Any sequences of partial updates to either policy entries or utilities will converge if every state is visited infinitely often
