#### **Bayes Filters**

Pieter Abbeel UC Berkeley EECS

Many slides adapted from Thrun, Burgard and Fox, Probabilistic Robotics

- Often the world is **dynamic** since
  - actions carried out by the robot,
  - actions carried out by other agents,
  - or just the time passing by

change the world.

How can we incorporate such actions?

## **Typical Actions**

- The robot turns its wheels to move
- The robot uses its manipulator to grasp an object
- Plants grow over time...

- Actions are never carried out with absolute certainty.
- In contrast to measurements, actions generally increase the uncertainty.

# Modeling Actions

 To incorporate the outcome of an action *u* into the current "belief", we use the conditional pdf

### *P(x|u,x')*

This term specifies the pdf that executing u changes the state from x' to x.

### Example: Closing the door

### **State Transitions**

P(x|u,x') for u = "close door":

If the door is open, the action "close door" succeeds in 90% of all cases.

### Integrating the Outcome of Actions

Continuous case:

$$P(x \mid u) = \int P(x \mid u, x') P(x') dx'$$

Discrete case:

$$P(x \mid u) = \sum P(x \mid u, x')P(x')$$

7

## Example: The Resulting Belief

$$P(closed | u) = \sum P(closed | u, x')P(x')$$

$$= P(closed | u, open)P(open)$$

$$+ P(closed | u, closed)P(closed)$$

$$= \frac{9}{10} * \frac{5}{8} + \frac{1}{1} * \frac{3}{8} = \frac{15}{16}$$

$$P(open | u) = \sum P(open | u, x')P(x')$$

$$= P(open | u, open)P(open)$$

$$+ P(open | u, closed)P(closed)$$

$$= \frac{1}{10} * \frac{5}{8} + \frac{0}{1} * \frac{3}{8} = \frac{1}{16}$$

$$= 1 - P(closed | u)$$

# Measurements

### Bayes rule

$$P(x|z) = \frac{P(z|x) P(x)}{P(z)} = \frac{\text{likelihood } \cdot \text{prior}}{\text{evidence}}$$

# **Bayes Filters: Framework**

#### Given:

- Stream of observations z and action data u:  $d_t = \{u_1, z_1, \dots, u_t, z_t\}$
- Sensor model P(z|x).
- Action model P(x|u,x').
- Prior probability of the system state P(x).
- Wanted:
  - Estimate of the state X of a dynamical system.
  - The posterior of the state is also called **Belief**:

$$Bel(x_t) = P(x_t | u_1, z_1 ..., u_t, z_t)$$

**Underlying Assumptions** 

- Static world
- Independent noise
- Perfect model, no approximation errors

### $Bel(x_t) = \eta P(z_t | x_t) \int P(x_t | u_t, x_{t-1}) Bel(x_{t-1}) dx_{t-1}$

I. Algorithm **Bayes\_filter**( *Bel(x),d* ):

$$2. \qquad \eta = 0$$

- 3. If *d* is a perceptual data item *z* then
- 4. For all x do

5. 
$$Bel'(x) = P(z \mid x)Bel(x)$$

$$\eta = \eta + Bel'(x)$$

7. For all x do

8. 
$$Bel'(x) = \eta^{-1}Bel'(x)$$

9. Else if *d* is an action data item *u* then

IO. For all x do

$$Bel'(x) = \int P(x \mid u, x') Bel(x') dx'$$

12. Return Bel'(x)

# **Example Applications**

- Robot localization:
  - Observations are range readings (continuous)
  - States are positions on a map (continuous)
- Speech recognition HMMs:
  - Observations are acoustic signals (continuous valued)
  - States are specific positions in specific words (so, tens of thousands)
- Machine translation HMMs:
  - Observations are words (tens of thousands)
  - States are translation options

# Summary

- Bayes rule allows us to compute probabilities that are hard to assess otherwise.
- Under the Markov assumption, recursive Bayesian updating can be used to efficiently combine evidence.
- Bayes filters are a probabilistic tool for estimating the state of dynamic systems.

Example from Michael Pfeiffer

Prob 0 t=0 1 Sensor model: never more than 1 mistake

Know the heading (North, East, South or West)

Motion model: may not execute action with small prob.

Lighter grey: was possible to get the reading, but less likely b/ c required 1 mistake

t=2
