LTC3108
Ultralow Voltage Step-Up Converter and Power Manager

FEATURES
- Operates from Inputs of 20mV
- Complete Energy Harvesting Power Management System
  - Selectable VOUT of 2.35V, 3.3V, 4.1V or 5V
  - LDO: 2.2V at 3mA
  - Logic Controlled Output
  - Reserve Energy Output
- Power Good Indicator
- Ultralow IQ: 6μA
- Uses Compact Step-Up Transformers
- Small 12-Lead (4mm × 3mm) DFN or 16-Lead SSOP Packages

APPLICATIONS
- Remote Sensors and Radio Power
- Surplus Heat Energy Harvesting
- HVAC
- Industrial Wireless Sensing
- Automatic Metering
- Building Automation
- Predictive Maintenance

DESCRIPTION
The LTC®3108 is a highly integrated DC/DC converter ideal for harvesting and managing surplus energy from extremely low input voltage sources such as TEGs (thermoelectric generators), thermopiles and small solar cells. The step-up topology operates from input voltages as low as 20mV.

Using a small step-up transformer, the LTC3108 provides a complete power management solution for wireless sensing and data acquisition. The 2.2V LDO powers an external microprocessor, while the main output is programmed to one of four fixed voltages to power a wireless transmitter or sensors. The power good indicator signals that the main output voltage is within regulation. A second output can be enabled by the host. A storage capacitor provides power when the input voltage source is unavailable. Extremely low quiescent current and high efficiency design ensure the fastest possible charge times of the output reservoir capacitor.

The LTC3108 is available in a small, thermally enhanced 12-lead (4mm × 3mm) DFN package and a 16-lead SSOP package.

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** The LTC3108E is guaranteed to meet performance specifications from 0°C to 85°C. Specifications over the –40°C to 85°C operating junction temperature range are assured by design, characterization and correlation with statistical process controls. The LTC3108I is guaranteed to meet specifications over the full –40°C to 85°C operating junction temperature range. Note that the maximum ambient temperature is determined by specific operating conditions in conjunction with board layout, the rated package thermal resistance and other environmental factors.

**Note 3:** Specification is guaranteed by design and not 100% tested in production.

**Note 4:** Failure to solder the exposed backside of the package to the PC board ground plane will result in a thermal resistance much higher than 43°C/W.

**Note 5:** The absolute maximum rating is a DC rating. Under certain conditions in the applications shown, the peak AC voltage on the C2 pin may exceed ±8V. This behavior is normal and acceptable because the current into the pin is limited by the impedance of the coupling capacitor.

**PIN FUNCTIONS** (DFN/SSOP)

**VAUX (Pin 1/Pin 2):** Output of the Internal Rectifier Circuit and $V_{CC}$ for the IC. Bypass VAUX with at least 1μF of capacitance. An active shunt regulator clamps VAUX to 5.25V (typical).

**VSTORE (Pin 2/Pin 3):** Output for the Storage Capacitor or Battery. A large capacitor may be connected from this pin to GND for powering the system in the event the input voltage is lost. It will be charged up to the maximum VAUX clamp voltage. If not used, this pin should be left open or tied to VAUX.

**VOUT (Pin 3/Pin 4):** Main Output of the Converter. The voltage at this pin is regulated to the voltage selected by VS1 and VS2 (see Table 1). Connect this pin to an energy storage capacitor or to a rechargeable battery.

**VOUT2 (Pin 4/Pin 5):** Switched Output of the Converter. Connect this pin to a switched load. This output is open until $V_{OUT2\_EN}$ is driven high, then it is connected to $V_{OUT}$ through a 1.3Ω P-channel switch. If not used, this pin should be left open or tied to $V_{OUT}$. The peak current in this output is limited to 0.3A typical.

**VLDO (Pin 5/Pin 6):** Output of the 2.2V LDO. Connect a 2.2μF or larger ceramic capacitor from this pin to GND. If not used, this pin should be tied to VAUX.

**PGD (Pin 6/Pin 7):** Power Good Output. When $V_{OUT}$ is within 7.5% of its programmed value, PGD will be pulled up to VLDO through a 1MΩ resistor. If $V_{OUT}$ drops 9% below its programmed value PGD will go low. This pin can sink up to 100μA.

**VS2 (Pin 7/Pin 10):** $V_{OUT}$ Select Pin 2. Connect this pin to ground or VAUX to program the output voltage (see Table 1).

**VS1 (Pin 8/Pin 11):** $V_{OUT}$ Select Pin 1. Connect this pin to ground or VAUX to program the output voltage (see Table 1).

**$V_{OUT2\_EN}$ (Pin 9/Pin 12):** Enable Input for $V_{OUT2}$. $V_{OUT2}$ will be enabled when this pin is driven high. There is an internal 5M pull-down resistor on this pin. If not used, this pin can be left open or grounded.

**C1 (Pin 10/Pin 13):** Input to the Charge Pump and Rectifier Circuit. Connect a capacitor from this pin to the secondary winding of the step-up transformer.

**C2 (Pin 11/Pin 14):** Input to the N-Channel Gate Drive Circuit. Connect a capacitor from this pin to the secondary winding of the step-up transformer.

**SW (Pin 12/Pin 15):** Drain of the Internal N-Channel Switch. Connect this pin to the primary winding of the transformer.

**GND (Pins 1, 8, 9, 16) SSOP Only:** Ground

**GND (Exposed Pad Pin 13) DFN Only:** Ground. The DFN exposed pad must be soldered to the PCB ground plane. It serves as the ground connection, and as a means of conducting heat away from the die.

The LTC3108 is designed to use a small external step-up transformer to create an ultralow input voltage step-up DC/DC converter and power manager. It is ideally suited for low power wireless sensors and other applications in which surplus energy harvesting is used to generate system power because traditional battery power is inconvenient or impractical.

The LTC3108 is designed to manage the charging and regulation of multiple outputs in a system in which the average power draw is very low, but there may be periodic pulses of higher load current required. This is typical of wireless sensor applications, where the quiescent power draw is extremely low most of the time, except for transmit bursts when circuitry is powered up to make measurements and transmit data.

The LTC3108 can also be used to trickle charge a standard capacitor, supercapacitor or rechargeable battery, using energy harvested from a Peltier or photovoltaic cell.
**OPERATION**

**Oscillator**

The LTC3108 utilizes a MOSFET switch to form a resonant step-up oscillator using an external step-up transformer and a small coupling capacitor. This allows it to boost input voltages as low as 20mV high enough to provide multiple regulated output voltages for powering other circuits. The frequency of oscillation is determined by the inductance of the transformer secondary winding and is typically in the range of 20kHz to 200kHz. For input voltages as low as 20mV, a primary-secondary turns ratio of about 1:100 is recommended. For higher input voltages, this ratio can be lower. See the Applications Information section for more information on selecting the transformer.

**Charge Pump and Rectifier**

The AC voltage produced on the secondary winding of the transformer is boosted and rectified using an external charge pump capacitor (from the secondary winding to pin C1) and the rectifiers internal to the LTC3108. The rectifier circuit feeds current into the VAUX pin, providing charge to the external VAUX capacitor and the other outputs.

**VAUX**

The active circuits within the LTC3108 are powered from VAUX, which should be bypassed with a 1μF capacitor. Larger capacitor values will reduce the ripple on VAUX but increase the time it takes for VAUX to rise and the other outputs to become active. Once VAUX exceeds 2.5V, the main VOUT is allowed to start charging.

An internal shunt regulator limits the maximum voltage on VAUX to 5.25V typical. It shunts to GND any excess current into VAUX when there is no load on the converter or the input source is generating more power than is required by the load.

**Voltage Reference**

The LTC3108 includes a precision, micropower reference, for accurate regulated output voltages. This reference becomes active as soon as VAUX exceeds 2V.

**Synchronous Rectifiers**

Once VAUX exceeds 2V, synchronous rectifiers in parallel with each of the internal diodes take over the job of rectifying the input voltage, improving efficiency.

**Low Dropout Linear Regulator (LDO)**

The LTC3108 includes a low current LDO to provide a regulated 2.2V output for powering low power processors or other low power ICs. The LDO is powered by the higher of VAUX or VOUT. This enables it to become active as soon as VAUX has charged to 2.3V, while the VOUT storage capacitor is still charging. In the event of a step load on the LDO output, current can come from the main VOUT capacitor if VAUX drops below VOUT. The LDO requires a 2.2μF ceramic capacitor for stability. Larger capacitor values can be used without limitation, but will increase the time it takes for all the outputs to charge up. The LDO output is current limited to 4mA minimum.

**VOUT**

The main output voltage on VOUT is charged from the VAUX supply, and is user programmed to one of four regulated voltages using the voltage select pins VS1 and VS2, according to Table 2. Although the logic threshold voltage for VS1 and VS2 is 0.85V typical, it is recommended that they be tied to ground or VAUX.

<table>
<thead>
<tr>
<th>VS2</th>
<th>VS1</th>
<th>VOUT</th>
</tr>
</thead>
<tbody>
<tr>
<td>GND</td>
<td>GND</td>
<td>2.35V</td>

<td>VAUX</td>
<td>3.3V</td>
</tr>
<tr>
<td>VAUX</td>
<td>GND</td>
<td>4.1V</td>
</tr>
<tr>
<td>VAUX</td>
<td>VAUX</td>
<td>5V</td>
</tr>
</tbody>
</table>

When the output voltage drops slightly below the regulated value, the charging current will be enabled as long as VAUX is greater than 2.5V. Once VOUT has reached the proper value, the charging current is turned off.

The internal programmable resistor divider sets VOUT, eliminating the need for very high value external resistors that are susceptible to board leakage.
OPERATION

In a typical application, a storage capacitor (typically a few hundred microfarads) is connected to VOUT. As soon as VAUX exceeds 2.5V, the VOUT capacitor will be allowed to charge up to its regulated voltage. The current available to charge the capacitor will depend on the input voltage and transformer turns ratio, but is limited to about 4.5mA typical.

PGOOD

A power good comparator monitors the VOUT voltage. The PGD pin is an open-drain output with a weak pull-up (1MΩ) to the LDO voltage. Once VOUT has charged to within 7.5% of its regulated voltage, the PGD output will go high. If VOUT drops more than 9% from its regulated voltage, PGD will go low. The PGD output is designed to drive a microprocessor or other chip I/O and is not intended to drive a higher current load such as an LED. Pulling PGD up externally to a voltage greater than VLDO will cause a small current to be sourced into VLDO. PGD can be pulled low in a wire-OR configuration with other circuitry.

VOUT2

VOUT2 is an output that can be turned on and off by the host, using the VOUT2_EN pin. When enabled, VOUT2 is connected to VOUT through a 1.3Ω P-channel MOSFET switch. This output, controlled by a host processor, can be used to power external circuits such as sensors and amplifiers, that do not have a low power sleep or shutdown capability. VOUT2 can be used to power these circuits only when they are needed.

Minimizing the amount of decoupling capacitance on VOUT2 will allow it to be switched on and off faster, allowing shorter burst times and, therefore, smaller duty cycles in pulsed applications such as a wireless sensor/transmitter. A small VOUT2 capacitor will also minimize the energy that will be wasted in charging the capacitor every time VOUT2 is enabled.

VOUT2 has a soft-start time of about 5μs to limit capacitor charging current and minimize glitching of the main output when VOUT2 is enabled. It also has a current limiting circuit that limits the peak current to 0.3A typical.

The VOUT2 enable input has a typical threshold of 1V with 100mV of hysteresis, making it logic-compatible. If VOUT2_EN (which has an internal pull-down resistor) is low, VOUT2 will be off. Driving VOUT2_EN high will turn on the VOUT2 output.

Note that while VOUT2_EN is high, the current limiting circuitry for VOUT2 draws an extra 8μA of quiescent current from VOUT. This added current draw has a negligible effect on the application and capacitor sizing, since the load on the VOUT2 output, when enabled, is likely to be orders of magnitude higher than 8μA.

VSTORE

The VSTORE output can be used to charge a large storage capacitor or rechargeable battery after VOUT has reached regulation. Once VOUT has reached regulation, the VSTORE output will be allowed to charge up to the VAUX voltage. The storage element on VSTORE can be used to power the system in the event that the input source is lost, or is unable to provide the current demanded by the VOUT, VOUT2 and LDO outputs. If VAUX drops below VSTORE, the LTC3108 will automatically draw current from the storage element. Note that it may take a long time to charge a large capacitor, depending on the input energy available and the loading on VOUT and VLDO.

Since the maximum current from VSTORE is limited to a few milliamps, it can safely be used to trickle-charge NiCd or NiMH rechargeable batteries for energy storage when the input voltage is lost. Note that the VSTORE capacitor cannot supply large pulse currents to VOUT. Any pulse load on VOUT must be handled by the VOUT capacitor.

Short-Circuit Protection

All outputs of the LTC3108 are current limited to protect against short-circuits to ground.

Output Voltage Sequencing

A timing diagram showing the typical charging and voltage sequencing of the outputs is shown in Figure 1. Note: time not to scale.
Figure 1. Output Voltage Sequencing with V_{OUT} Programmed for 3.3V (Time Not to Scale)
**APPLICATIONS INFORMATION**

**Introduction**

The LTC3108 is designed to gather energy from very low input voltage sources and convert it to usable output voltages to power microprocessors, wireless transmitters and analog sensors. Such applications typically require much more peak power, and at higher voltages, than the input voltage source can produce. The LTC3108 is designed to accumulate and manage energy over a long period of time to enable short power bursts for acquiring and transmitting data. The bursts must occur at a low enough duty cycle such that the total output energy during the burst does not exceed the average source power integrated over the accumulation time between bursts. For many applications, this time between bursts could be seconds, minutes or hours.

The PGD signal can be used to enable a sleeping microprocessor or other circuitry when $V_{OUT}$ reaches regulation, indicating that enough energy is available for a burst.

**Input Voltage Sources**

The LTC3108 can operate from a number of low input voltage sources, such as Peltier cells, photovoltaic cells or thermopile generators. The minimum input voltage required for a given application will depend on the transformer turns ratio, the load power required, and the internal DC resistance (ESR) of the voltage source. Lower ESR will allow the use of lower input voltages, and provide higher output power capability.

For a given transformer turns ratio, there is a maximum recommended input voltage to avoid excessively high secondary voltages and power dissipation in the shunt regulator. It is recommended that the maximum input voltage times the turns ratio be less than 50.

Note that a low ESR bulk decoupling capacitor will usually be required across the input source to prevent large voltage droop and ripple caused by the source’s ESR and the peak primary switching current (which can reach hundreds of milliamps). The time constant of the filter capacitor and the ESR of the voltage source should be much longer than the period of the resonant switching frequency.

**Peltier Cell (Thermoelectric Generator)**

A Peltier cell (also known as a thermoelectric cooler) is made up of a large number of series-connected P-N junctions, sandwiched between two parallel ceramic plates. Although Peltier cells are often used as coolers by applying a DC voltage to their inputs, they will also generate a DC output voltage, using the Seebeck effect, when the two plates are at different temperatures. The polarity of the output voltage will depend on the polarity of the temperature differential between the plates. The magnitude of the output voltage is proportional to the magnitude of the temperature differential between the plates. When used in this manner, a Peltier cell is referred to as a thermoelectric generator (TEG).

![Figure 2. Typical Performance of a Peltier Cell Acting as a Thermoelectric Generator](image-url)
APPLICATIONS INFORMATION

The low voltage capability of the LTC3108 design allows it to operate from a TEG with temperature differentials as low as 1°C, making it ideal for harvesting energy in applications in which a temperature difference exists between two surfaces or between a surface and the ambient temperature. The internal resistance (ESR) of most cells is in the range of 1Ω to 5Ω, allowing for reasonable power transfer. The curves in Figure 2 show the open-circuit output voltage and maximum power transfer for a typical Peltier cell (with an ESR of 2Ω) over a 20°C range of temperature differential.

TEG Load Matching

The LTC3108 was designed to present a minimum input resistance (load) in the range of 2Ω to 10Ω, depending on input voltage and transformer turns ratio (as shown in the Typical Performance Characteristics curves). For a given turns ratio, as the input voltage drops, the input resistance increases. This feature allows the LTC3108 to optimize power transfer from sources with a few ohms of source resistance, such as a typical TEG. Note that a lower source resistance will always provide more output current capability by providing a higher input voltage under load.

Peltier Cell (TEG) Suppliers

Peltier cells are available in a wide range of sizes and power capabilities, from less than 10mm square to over 50mm square. They are typically 2mm to 5mm in height. A list of Peltier cell manufacturers is given in Table 3.

Thermopile Generator

Thermopile generators (also called powerpile generators) are made up of a number of series-connected thermocouples enclosed in a metal tube. They are commonly used in gas burner applications to generate a DC output of hundreds of millivolts when exposed to the high temperature of a flame. Typical examples are the Honeywell CQ200 and Q313. These devices have an internal series resistance of less than 3Ω, and can generate as much as 750mV open-circuit at their highest rated temperature. For applications in which the temperature rise is too high for a solid-state thermoelectric device, a thermopile can be used as an energy source to power the LTC3108. Because of the higher output voltages possible with a thermopile generator, a much lower transformer turns ratio can be used (typically 1:20, depending on the application).

Photovoltaic Cell

The LTC3108 converter can also operate from a single photovoltaic (solar) cell operating in indoor lighting, where the available power is orders of magnitude less than in direct sunlight. This capability allows the LTC3108 to power circuits at light levels far too low for even very low input voltage boost converters.

Non-Boost Applications

The LTC3108 can also be used as an energy harvester and power manager for input sources that do not require boosting. In these applications the step-up transformer can be eliminated.

Any source whose peak voltage exceeds 2.5V AC or 5V DC can be connected to the C1 input through a current-limiting resistor where it will be rectified/peak detected. In these applications the C2 and SW pins are not used and can be grounded or left open.

Examples of such input sources would be piezoelectric transducers, vibration energy harvesters, low current generators, a stack of low current solar cells or a 60Hz AC input.

A series resistance of at least 100Ω/V should be used to limit the maximum current into the VAUX shunt regulator.
APPLICATIONS INFORMATION

COMPONENT SELECTION

Step-Up Transformer

The step-up transformer turns ratio will determine how low the input voltage can be for the converter to start. Using a 1:100 ratio can yield start-up voltages as low as 20mV. Other factors that affect performance are the DC resistance of the transformer windings and the inductance of the windings. Higher DC resistance will result in lower efficiency. The secondary winding inductance will determine the resonant frequency of the oscillator, according to the following formula.

\[
\text{Frequency} = \frac{1}{2 \cdot \pi \cdot \sqrt{L \cdot \text{sec} \cdot C}} \text{ Hz}
\]

Where L is the inductance of the transformer secondary winding and C is the load capacitance on the secondary winding. This is comprised of the input capacitance at pin C2, typically 30pF, in parallel with the transformer secondary winding’s shunt capacitance. The recommended resonant frequency is in the range of 20kHz to 200kHz. See Table 4 for some recommended transformers.

C1 Capacitor

The charge pump capacitor that is connected from the transformer’s secondary winding to the C1 pin has an effect on converter input resistance and maximum output current capability. Generally, a minimum value of 1nF is recommended when operating from very low input voltages using a transformer with a ratio of 1:100. Too large a capacitor value can compromise performance when operating at low input voltage or with high resistance sources. For higher input voltages and lower turns ratios, the value of the C1 capacitor can be increased for higher output current capability. Refer to the Typical Applications schematic examples for the recommended value for a given turns ratio.

V_{OUT} and VSTORE Capacitor

For pulsed load applications, the V_{OUT} capacitor should be sized to provide the necessary current when the load is pulsed on. The capacitor value required will be dictated by the load current, the duration of the load pulse, and the amount of voltage droop the circuit can tolerate. The capacitor must be rated for whatever voltage has been selected for V_{OUT} by VS1 and VS2.

\[
C_{\text{OUT}}(\text{mF}) \geq \frac{I_{\text{LOAD}}(\text{mA}) \cdot t_{\text{PULSE}}(\text{sec})}{\Delta V_{\text{OUT}}}
\]

Note that there must be enough energy available from the input voltage source for V_{OUT} to recharge the capacitor during the interval between load pulses (to be discussed in the next example). Reducing the duty cycle of the load pulse will allow operation with less input energy.

The VSTORE capacitor may be of very large value (thousands of microfarads or even Farads), to provide holdup at times when the input power may be lost. Note that this capacitor can charge all the way to 5.25V (regardless of the settings for V_{OUT}), so ensure that the holdup capacitor has a working voltage rating of at least 5.5V at the temperature for which it will be used. The VSTORE capacitor can be sized using the following:

\[
C_{\text{STORE}} \geq \left[\frac{6 \mu A + I_Q + I_{\text{LDO}} + (I_{\text{BURST}} \cdot t \cdot f)}{5.25 - V_{\text{OUT}}}\right] \cdot T_{\text{STORE}}
\]

Where 6μA is the quiescent current of the LTC3108, I_Q is the load on V_{OUT} in between bursts, I_{LDO} is the load on the LDO between bursts, I_{BURST} is the total load during the burst, t is the duration of the burst, f is the frequency of the bursts, TSTORE is the storage time required and V_{OUT} is the output voltage required. Note that for a programmed output voltage of 5V, the VSTORE capacitor cannot provide any beneficial storage time.
To minimize losses and capacitor charge time, all capacitors used for VOUT and VSTORE should be low leakage. See Table 5 for recommended storage capacitors.

Storage capacitors requiring voltage balancing are not recommended due to the current draw of the balancing resistors.

PCB Layout Guidelines

Due to the rather low switching frequency of the resonant converter and the low power levels involved, PCB layout is not as critical as with many other DC/DC converters. There are, however, a number of things to consider.

Due to the very low input voltage the circuit may operate from, the connections to V_IN, the primary of the transformer and the SW and GND pins of the LTC3108 should be designed to minimize voltage drop from stray resistance and able to carry currents as high as 500mA. Any small voltage drop in the primary winding conduction path will lower efficiency and increase capacitor charge time.

Also, due to the low charge currents available at the outputs of the LTC3108, any sources of leakage current on the output voltage pins must be minimized. An example board layout is shown in Figure 3.

Design Example 1

This design example will explain how to calculate the necessary storage capacitor value for VOUT in pulsed load applications, such as a wireless sensor/transmitter. In these types of applications, the load is very small for a majority of the time (while the circuitry is in a low power sleep state), with bursts of load current occurring periodically during a transmit burst. The storage capacitor on VOUT supports the load during the transmit burst, and the long sleep time between bursts allows the LTC3108 to recharge...
the capacitor. A method for calculating the maximum rate at which the load pulses can occur for a given output current from the LTC3108 will also be shown.

In this example, $V_{OUT}$ is set to 3.3V, and the maximum allowed voltage droop during a transmit burst is 10%, or 0.33V. The duration of a transmit burst is 1ms, with a total average current requirement of 40mA during the burst. Given these factors, the minimum required capacitance on $V_{OUT}$ is:

$$C_{OUT} (\mu F) \geq \frac{40mA \cdot 1ms}{0.33V} = 121\mu F$$

Note that this equation neglects the effect of capacitor ESR on output voltage droop. For most ceramic or low ESR tantalum capacitors, the ESR will have a negligible effect at these load currents.

A standard value of 150μF or larger could be used for $C_{OUT}$ in this case. Note that the load current is the total current draw on $V_{OUT}$, $V_{OUT2}$ and $VLDO$, since the current for all of these outputs must come from $V_{OUT}$ during a burst. Current contribution from the holdup capacitor on $V_{STORE}$ is not considered, since it may not be able to recharge between bursts. Also, it is assumed that the charge current from the LTC3108 is negligible compared to the magnitude of the load current during the burst.

To calculate the maximum rate at which load bursts can occur, determine how much charge current is available from the LTC3108 $V_{OUT}$ pin given the input voltage source being used. This number is best found empirically, since there are many factors affecting the efficiency of the converter. Also determine what the total load current is on $V_{OUT}$ during the sleep state (between bursts). Note that this must include any losses, such as storage capacitor leakage.

Assume, for instance, that the charge current from the LTC3108 is 50μA and the total current drawn on $V_{OUT}$ in the sleep state is 17μA, including capacitor leakage. In addition, use the value of 150μF for the $V_{OUT}$ capacitor. The maximum transmit rate (neglecting the duration of the transmit burst, which is typically very short) is then given by:

$$t = \frac{150\mu F \cdot 0.33V}{(50\mu A - 17\mu A)} = 1.5sec$$

Therefore, in this application example, the circuit can support a 1ms transmit burst every 1.5 seconds.

It can be determined that for systems that only need to transmit every few seconds (or minutes or hours), the average charge current required is extremely small, as long as the sleep current is low. Even if the available charge current in the example above was only 10μA and the sleep current was only 5μA, it could still transmit a burst every ten seconds.

The following formula enables the user to calculate the time it will take to charge the LDO output capacitor and the $V_{OUT}$ capacitor the first time, from 0V. Here again, the charge current available from the LTC3108 must be known. For this calculation, it is assumed that the LDO output capacitor is 2.2μF.

$$t_{LDO} = \frac{2.2V \cdot 2.2\mu F}{I_{CHG} - I_{LDO}}$$

If there were 50μA of charge current available and a 5μA load on the LDO (when the processor is sleeping), the time for the LDO to reach regulation would be 107ms.

If $V_{OUT}$ were programmed to 3.3V and the $V_{OUT}$ capacitor was 150μF, the time for $V_{OUT}$ to reach regulation would be:

$$t_{VOUT} = \frac{3.3V \cdot 150\mu F}{I_{CHG} - I_{VOUT}} + t_{LDO}$$

If there were 50μA of charge current available and 5μA of load on $V_{OUT}$, the time for $V_{OUT}$ to reach regulation after the initial application of power would be 11.1 seconds.
**APPLICATIONS INFORMATION**

**Design Example 2**

In many pulsed load applications, the duration, magnitude and frequency of the load current bursts are known and fixed. In these cases, the average charge current required from the LTC3108 to support the average load must be calculated, which can be easily done by the following:

\[ I_{CHG} \geq I_Q + \frac{I_{BURST} \cdot t}{T} \]

Where \( I_Q \) is the sleep current on \( V_{OUT} \) required by the external circuitry in between bursts (including cap leakage), \( I_{BURST} \) is the total load current during the burst, \( t \) is the duration of the burst and \( T \) is the period of the transmit burst rate (essentially the time between bursts).

In this example, \( I_Q = 5\mu A \), \( I_{BURST} = 100mA \), \( t = 5ms \) and \( T = \) one hour. The average charge current required from the LTC3108 would be:

\[ I_{CHG} \geq 5\mu A + \frac{100mA \cdot 0.005sec}{3600sec} = 5.14\mu A \]

Therefore, if the LTC3108 has an input voltage that allows it to supply a charge current greater than 5.14\( \mu A \), the application can support 100mA bursts lasting 5ms every hour. It can be determined that the sleep current of 5\( \mu A \) is the dominant factor because the transmit duty cycle is so small (0.00014\%). Note that for a \( V_{OUT} \) of 3.3V, the average power required by this application is only 17\( \mu W \) (not including converter losses).

Note that the charge current available from the LTC3108 has no effect on the sizing of the \( V_{OUT} \) capacitor (if it is assumed that the load current during a burst is much larger than the charge current), and the \( V_{OUT} \) capacitor has no effect on the maximum allowed burst rate.

**TYPICAL APPLICATIONS**

Peltier-Powered Energy Harvester for Remote Sensor Applications

Therefore, if the LTC3108 has an input voltage that allows it to supply a charge current greater than 5.14\( \mu A \), the application can support 100mA bursts lasting 5ms every hour. It can be determined that the sleep current of 5\( \mu A \) is the dominant factor because the transmit duty cycle is so small (0.00014\%). Note that for a \( V_{OUT} \) of 3.3V, the average power required by this application is only 17\( \mu W \) (not including converter losses).

Note that the charge current available from the LTC3108 has no effect on the sizing of the \( V_{OUT} \) capacitor (if it is assumed that the load current during a burst is much larger than the charge current), and the \( V_{OUT} \) capacitor has no effect on the maximum allowed burst rate.
