Outline

◊ Learning agents
◊ Inductive learning
◊ Decision tree learning
◊ Measuring learning performance
Learning

Learning is essential for unknown environments, i.e., when designer lacks omniscience

Learning is useful as a system construction method, i.e., expose the agent to reality rather than trying to write it down

Learning modifies the agent’s decision mechanisms to improve performance
Learning agents

experiments

Chapter 18, Sections 1–3
Design of learning element is dictated by

- what type of performance element is used
- which functional component is to be learned
- how that functional component is represented
- what kind of feedback is available

Example scenarios:

<table>
<thead>
<tr>
<th>Performance element</th>
<th>Component</th>
<th>Representation</th>
<th>Feedback</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alpha–beta search</td>
<td>Eval. fn.</td>
<td>Weighted linear function</td>
<td>Win/loss</td>
</tr>
<tr>
<td>Logical agent</td>
<td>Transition model</td>
<td>Successor–state axioms</td>
<td>Outcome</td>
</tr>
<tr>
<td>Utility–based agent</td>
<td>Transition model</td>
<td>Dynamic Bayes net</td>
<td>Outcome</td>
</tr>
<tr>
<td>Simple reflex agent</td>
<td>Percept–action fn</td>
<td>Neural net</td>
<td>Correct action</td>
</tr>
</tbody>
</table>

*Supervised learning*: correct answers for each instance
*Reinforcement learning*: occasional rewards
Inductive learning (a.k.a. Science)

Simplest form: learn a function from examples (tabula rasa)

\( f \) is the target function

An example is a pair \( x, f(x) \), e.g.,

\[
\begin{array}{c|c|c}
O & O & X \\
\hline
X & X & \text{+1} \\
\end{array}
\]

Problem: find a(n) hypothesis \( h \) such that \( h \approx f \)
given a training set of examples

(This is a highly simplified model of real learning:
- Ignores prior knowledge
- Assumes a deterministic, observable “environment”
- Assumes examples are given
- Assumes that the agent wants to learn \( f \)—why?)
Inductive learning method

Construct/adjust \( h \) to agree with \( f \) on training set
\( (h \) is consistent if it agrees with \( f \) on all examples)\)

E.g., curve fitting:

\[
f(x)
\]

\[
\begin{array}{c}
\text{x} \\
\text{f(x)}
\end{array}
\]
Inductive learning method

Construct/adjust $h$ to agree with $f$ on training set ($h$ is consistent if it agrees with $f$ on all examples)

E.g., curve fitting:
Inductive learning method

Construct/adjust $h$ to agree with $f$ on training set
($h$ is consistent if it agrees with $f$ on all examples)

E.g., curve fitting:

\[ f(x) \]

\[ x \]
Inductive learning method

Construct/adjust $h$ to agree with $f$ on training set
($h$ is consistent if it agrees with $f$ on all examples)

E.g., curve fitting:

\[ f(x) \]
Inductive learning method

Construct/adjust $h$ to agree with $f$ on training set
($h$ is consistent if it agrees with $f$ on all examples)

E.g., curve fitting:

![Diagram of curve fitting]
Inductive learning method

Construct/adjust $h$ to agree with $f$ on training set
($h$ is consistent if it agrees with $f$ on all examples)

E.g., curve fitting:

Ockham’s razor: maximize a combination of consistency and simplicity
### Attribute-based representations

Examples described by **attribute values** (Boolean, discrete, continuous, etc.)

E.g., situations where I will/won’t wait for a table:

<table>
<thead>
<tr>
<th>Example</th>
<th>Attributes</th>
<th>Target</th>
<th>WillWait</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Alt Bar Fri Hun Pat Price Rain Res Type Est</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$X_1$</td>
<td>T F F T Some $$$ F T French 0–10</td>
<td>T</td>
<td></td>
</tr>
<tr>
<td>$X_2$</td>
<td>T F F T Full $ F F Thai 30–60</td>
<td>F</td>
<td></td>
</tr>
<tr>
<td>$X_3$</td>
<td>F T F F Some $ F F Burger 0–10</td>
<td>T</td>
<td></td>
</tr>
<tr>
<td>$X_4$</td>
<td>T F T T Full $ F F Thai 10–30</td>
<td>T</td>
<td></td>
</tr>
<tr>
<td>$X_5$</td>
<td>T F T F Full $$$ F T French &gt;60</td>
<td>F</td>
<td></td>
</tr>
<tr>
<td>$X_6$</td>
<td>F T F T Some $$$ T T Italian 0–10</td>
<td>T</td>
<td></td>
</tr>
<tr>
<td>$X_7$</td>
<td>F T F F None $ T F Burger 0–10</td>
<td>F</td>
<td></td>
</tr>
<tr>
<td>$X_8$</td>
<td>F F F T Some $$$ T T Thai 0–10</td>
<td>T</td>
<td></td>
</tr>
<tr>
<td>$X_9$</td>
<td>F T T F Full $ T F Burger &gt;60</td>
<td>F</td>
<td></td>
</tr>
<tr>
<td>$X_{10}$</td>
<td>T T T T Full $$$ F T Italian 10–30</td>
<td>F</td>
<td></td>
</tr>
<tr>
<td>$X_{11}$</td>
<td>F F F F None $ F F Thai 0–10</td>
<td>F</td>
<td></td>
</tr>
<tr>
<td>$X_{12}$</td>
<td>T T T T Full $ F F Burger 30–60</td>
<td>T</td>
<td></td>
</tr>
</tbody>
</table>

**Classification** of examples is **positive** (T) or **negative** (F)
Decision trees

One possible representation for hypotheses
E.g., here is the “true” tree for deciding whether to wait:

```
Patrons?
  None  Some  Full
    |      |      |
    F     T     |

WaitEstimate?
  >60  30–60  10–30
    |      |      |
    F     T     T

Alternate?
  No  Yes
    |      |
    F     T

Hungry?
  No  Yes
    |      |
    T     T

Reservation?
  No  Yes
    |      |
    T     T

Fri/Sat?
  No  Yes
    |      |
    T     T

Bar?
  No  Yes
    |      |
    F     T

Alternate?
  No  Yes
    |      |
    T     T

Raining?
  No  Yes
    |      |
    F     T
```
Expressiveness

Decision trees can express any function of the input attributes. E.g., for Boolean functions, truth table row $\rightarrow$ path to leaf:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>$A \text{ xor } B$</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>F</td>
<td>F</td>
</tr>
<tr>
<td>F</td>
<td>T</td>
<td>T</td>
</tr>
<tr>
<td>T</td>
<td>F</td>
<td>T</td>
</tr>
<tr>
<td>T</td>
<td>T</td>
<td>F</td>
</tr>
</tbody>
</table>

Trivially, there is a consistent decision tree for any training set w/ one path to leaf for each example (unless $f$ nondeterministic in $x$) but it probably won’t generalize to new examples.

Prefer to find more **compact** decision trees.
Hypothesis spaces

How many distinct decision trees with $n$ Boolean attributes?
Hypothesis spaces

How many distinct decision trees with \( n \) Boolean attributes?

= number of Boolean functions
Hypothesis spaces

How many distinct decision trees with $n$ Boolean attributes?

= number of Boolean functions
= number of distinct truth tables with $2^n$ rows
Hypothesis spaces

How many distinct decision trees with \( n \) Boolean attributes?

\[ = \text{number of Boolean functions} \]
\[ = \text{number of distinct truth tables with } 2^n \text{ rows} = 2^{2^n} \]
Hypothesis spaces

How many distinct decision trees with $n$ Boolean attributes?

= number of Boolean functions
= number of distinct truth tables with $2^n$ rows = $2^{2n}$

E.g., with 6 Boolean attributes, there are 18,446,744,073,709,551,616 trees
Hypothesis spaces

How many distinct decision trees with $n$ Boolean attributes?

$= \text{number of Boolean functions}$
$= \text{number of distinct truth tables with } 2^n \text{ rows } = 2^{2^n}$

E.g., with 6 Boolean attributes, there are $18,446,744,073,709,551,616$ trees

How many purely conjunctive hypotheses (e.g., $Hungry \land \neg Rain$)?
Hypothesis spaces

How many distinct decision trees with $n$ Boolean attributes??

$= \text{number of Boolean functions}$

$= \text{number of distinct truth tables with } 2^n \text{ rows } = 2^{2^n}$

E.g., with 6 Boolean attributes, there are $18,446,744,073,709,551,616$ trees

How many purely conjunctive hypotheses (e.g., $Hungry \land \neg Rain$)??

Each attribute can be in (positive), in (negative), or out

$\Rightarrow 3^n$ distinct conjunctive hypotheses

More expressive hypothesis space

- increases chance that target function can be expressed
- increases number of hypotheses consistent w/ training set

$\Rightarrow$ may get worse predictions
Decision tree learning

Aim: find a small tree consistent with the training examples

Idea: (recursively) choose “most significant” attribute as root of (sub)tree

```
function DTL(examples, attributes, default) returns a decision tree
    if examples is empty then return default
    else if all examples have the same classification then return the classification
    else if attributes is empty then return Mode(examples)
    else
        best ← CHOOSE-ATTRIBUTE(attributes, examples)
        tree ← a new decision tree with root test best
        for each value $v_i$ of best do
            examples_i ← {elements of examples with best = $v_i$}
            subtree ← DTL(examples_i, attributes − best, Mode(examples))
            add a branch to tree with label $v_i$ and subtree subtree
        end for
    end if
    return tree
```
Choosing an attribute

Idea: a good attribute splits the examples into subsets that are (ideally) “all positive” or “all negative”

Patrons? is a better choice—gives information about the classification
Information

Information answers questions

The more clueless I am about the answer initially, the more information is contained in the answer

Scale: 1 bit = answer to Boolean question with prior \( \langle 0.5, 0.5 \rangle \)

Information in an answer when prior is \( \langle P_1, \ldots, P_n \rangle \) is

\[
H(\langle P_1, \ldots, P_n \rangle) = \sum_{i=1}^{n} - P_i \log_2 P_i
\]

(also called entropy of the prior)
Suppose we have \( p \) positive and \( n \) negative examples at the root

\[
\Rightarrow H\left(\frac{p}{p+n}, \frac{n}{p+n}\right) \text{ bits needed to classify a new example}
\]

E.g., for 12 restaurant examples, \( p = n = 6 \) so we need 1 bit

An attribute splits the examples \( E \) into subsets \( E_i \), each of which (we hope) needs less information to complete the classification

Let \( E_i \) have \( p_i \) positive and \( n_i \) negative examples

\[
\Rightarrow H\left(\frac{p_i}{p_i+n_i}, \frac{n_i}{p_i+n_i}\right) \text{ bits needed to classify a new example}
\]

\[
\Rightarrow \text{expected number of bits per example over all branches is}
\]

\[
\sum_i \frac{p_i + n_i}{p + n} H\left(\frac{p_i}{p_i+n_i}, \frac{n_i}{p_i+n_i}\right)
\]

For *Patrons?*, this is 0.459 bits, for *Type* this is (still) 1 bit

\[
\Rightarrow \text{choose the attribute that minimizes the remaining information needed}
\]
Decision tree learned from the 12 examples:

Substantially simpler than “true” tree—a more complex hypothesis isn’t justified by small amount of data
Performance measurement

How do we know that \( h \approx f \)? (Hume’s **Problem of Induction**)

1) Use theorems of computational/statistical learning theory

2) Try \( h \) on a new test set of examples
   (use **same distribution over example space** as training set)

**Learning curve** = \% correct on test set as a function of training set size

![Learning curve graph](image.png)
Performance measurement contd.

Learning curve depends on

- **realizable** (can express target function) vs. **non-realizable**
  
  non-realizability can be due to missing attributes
  
  or restricted hypothesis class (e.g., thresholded linear function)

- redundant expressiveness (e.g., loads of irrelevant attributes)
Summary

Learning needed for unknown environments, lazy designers

Learning agent = performance element + learning element

Learning method depends on type of performance element, available feedback, type of component to be improved, and its representation

For supervised learning, the aim is to find a simple hypothesis that is approximately consistent with training examples

Decision tree learning using information gain

Learning performance = prediction accuracy measured on test set
