Uncertainty
Chapter 13

Outline
- Uncertainty
- Probability
- Syntax and Semantics
- Inference
- Independence and Bayes' Rule

Methods for handling uncertainty

Default or nonmonotonic logic:
- Assume my car does not have a flat tire
- Assume $A_{25}$ works unless contradicted by evidence
Issues: What assumptions are reasonable? How to handle contradiction?

Rules with fudge factors:
- $A_{25} \rightarrow_{WF} \text{AirportOnTime}$
- $\text{Sprinkler} \rightarrow_{WF} \text{WetGrass}$
- $\text{WetGrass} \rightarrow_{WF} \text{Rain}$
Issues: Problems with combination, e.g., $\text{Sprinkler}$ causes $\text{Rain}$?

Probability
- Given the available evidence, $A_{25}$ will get me there on time with probability $0.04$
- Mahaviracarya (9th C.), Cardamo (1565) theory of gambling
(Fuzzy logic handles degree of truth NOT uncertainty e.g., $\text{WetGrass}$ is true to degree $0.2$)

Probability
Probabilistic assertions summarize effects of
- laziness: failure to enumerate exceptions, qualifications, etc.
- ignorance: lack of relevant facts, initial conditions, etc.

Subjective or Bayesian probability:
- Probabilities relate propositions to one's own state of knowledge
  e.g., $P(A_{25}|\text{no reported accidents}) = 0.06$
- These are not claims of a "probabilistic tendency" in the current situation
  (but might be learned from past experience of similar situations)
- Probabilities of propositions change with new evidence:
  e.g., $P(A_{25}|\text{no reported accidents, 5 a.m.}) = 0.15$
  (Analogous to logical entailment status $KB \models \alpha$, not truth.)

Making decisions under uncertainty
Suppose I believe the following:
- $P(A_{25} \text{ gets me there on time | . . . } ) = 0.04$
- $P(A_{40} \text{ gets me there on time | . . . } ) = 0.70$
- $P(A_{120} \text{ gets me there on time | . . . } ) = 0.95$
- $P(A_{1440} \text{ gets me there on time | . . . } ) = 0.9999$
Which action to choose?
- Depends on my preferences for missing flight vs. airport cuisine, etc.
- Utility theory is used to represent and infer preferences
- Decision theory = utility theory + probability theory

Uncertainty
Let action $A_t = \text{ leave for airport } t \text{ minutes before flight}$
Will $A_t$ get me there on time?
Problems:
- 1) partial observability (road state, other drivers' plans, etc.)
- 2) noisy sensors (KCBS traffic reports)
- 3) uncertainty in action outcomes (flat tire, etc.)
- 4) immense complexity of modelling and predicting traffic
Hence a purely logical approach either
- 1) risks falsehood: "$A_{25}$ will get me there on time"
- 2) leads to conclusions that are too weak for decision making:
  "$A_{25}$ will get me there on time if there's no accident on the bridge
  and it doesn't rain and my tires remain intact etc etc."
($A_{1440}$ might reasonably be said to get me there on time
but I'd have to stay overnight in the airport . . .)
Probability basics

Begin with a set $\Omega$—the sample space

- e.g., 6 possible rolls of a die.
  
  $\omega \in \Omega$ is a sample point/possible world/atomic event

A probability space or probability model is a sample space with an assignment $P(\omega)$ for every $\omega \in \Omega$ s.t.

- $0 \leq P(\omega) \leq 1$
- $\sum_{\omega} P(\omega) = 1$

An event $A$ is any subset of $\Omega$

$$P(A) = \sum_{\omega \in A} P(\omega)$$

E.g., $P(\text{die roll} < 4) = P(1) + P(2) + P(3) = 1/6 + 1/6 + 1/6 = 1/2$

Random variables

A random variable is a function from sample points to some range, e.g., the reals or Booleans

- e.g., $\text{Odd}(1) = \text{true}$.

$P$ induces a probability distribution for any r.v. $X$:

$$P(X = x_i) = \sum_{\omega \mid X(\omega) = x_i} P(\omega)$$

e.g., $P(\text{Odd} = \text{true}) = P(1) + P(3) + P(5) = 1/6 + 1/6 + 1/6 = 1/2$

Syntax for propositions

Propositional or Boolean random variables

- e.g., $\text{Cavity}$ (do I have a cavity?)

  $\text{Cavity} = \text{true}$ is a proposition, also written $\text{cavity}$

Discrete random variables (finite or infinite)

- e.g., $\text{Weather}$ is one of (sunny, rain, cloudy, snow)

  $\text{Weather} = \text{rain}$ is a proposition

Values must be exhaustive and mutually exclusive

Continuous random variables (bounded or unbounded)

- e.g., $\text{Temp} = 21.6$; also allow, e.g., $\text{Temp} < 22.0$.

Arbitrary Boolean combinations of basic propositions

Propositions

Think of a proposition as the event (set of sample points) where the proposition is true

Given Boolean random variables $A$ and $B$:

- event $a$ = set of sample points where $A(\omega) = \text{true}$
- event $\neg a$ = set of sample points where $A(\omega) = \text{false}$
- event $a \land b$ = points where $A(\omega) = \text{true}$ and $B(\omega) = \text{true}$

Often in AI applications, the sample points are defined by the values of a set of random variables, i.e., the sample space is the Cartesian product of the ranges of the variables

With Boolean variables, sample point = propositional logic model

- e.g., $A = \text{true}$, $B = \text{false}$, or $a \land \neg b$.

Proposition = disjunction of atomic events in which it is true

- e.g., $(a \lor b) \equiv (\neg a \land b) \lor (a \land \neg b) \lor (a \land b)$

$\Rightarrow P(a \lor b) = P(\neg a \land b) + P(a \land \neg b) + P(a \land b)$

Prior probability

Prior or unconditional probabilities of propositions

- e.g., $P(\text{Cavity} = \text{true}) = 0.1$ and $P(\text{Weather} = \text{sunny}) = 0.72$

  correspond to belief prior to arrival of any (new) evidence

Probability distribution gives values for all possible assignments:

$$P(\text{Weather}) = (0.72, 0.1, 0.08, 0.1)$$

(normalized, i.e., sums to 1)

Joint probability distribution for a set of r.v.s gives the probability of every atomic event on those r.v.s (i.e., every sample point)

$$P(\text{Weather}, \text{Cavity}) = 4 \times 2$$

matrix of values:

<table>
<thead>
<tr>
<th>Weather</th>
<th>sunny</th>
<th>rain</th>
<th>cloudy</th>
<th>snow</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cavity = true</td>
<td>0.144</td>
<td>0.02</td>
<td>0.016</td>
<td>0.02</td>
</tr>
<tr>
<td>Cavity = false</td>
<td>0.576</td>
<td>0.08</td>
<td>0.064</td>
<td>0.08</td>
</tr>
</tbody>
</table>

Every question about a domain can be answered by the joint distribution because every event is a sum of sample points
Probability for continuous variables

Express distribution as a parameterized function of value:
\[ P(X = x) = \begin{cases} U[18, 26](x) & \text{uniform density between 18 and 26} \end{cases} \]

Here \( P \) is a density; integrates to 1.
\[ P(X = 20.5) = 0.125 \]

Gaussian density

\[ P(x) = \frac{1}{\sqrt{2\pi \sigma}}e^{-\frac{(x-\mu)^2}{2\sigma^2}} \]

Inference by enumeration

Start with the joint distribution:

<table>
<thead>
<tr>
<th>cavity</th>
<th>catch</th>
<th>toothache</th>
<th>¬ toothache</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>.108</td>
<td>.012</td>
<td>.016</td>
</tr>
<tr>
<td>¬ cavity</td>
<td>.016</td>
<td>.064</td>
<td>.144</td>
</tr>
</tbody>
</table>

For any proposition \( \phi \), sum the atomic events where it is true:
\[ P(\phi) = \sum_{\omega \in \Omega} P(\omega) \]

Conditional probability

Conditional or posterior probabilities
\[ e.g., P(\text{cavity} | \text{toothache}) = 0.8 \]
i.e., given that toothache is all I know

NOT "if toothache then 80% chance of cavity"

(Notation for conditional distributions:
\[ P(\text{Cavity} | \text{Toothache}) = 2\text{-element vector of 2\text{-element vectors}} \]

If we know more, e.g., cavity is also given, then we have
\[ P(\text{cavity} | \text{toothache}, \text{cavity}) = 1 \]

Note: the less specific belief remains valid after more evidence arrives, but is not always useful

New evidence may be irrelevant, allowing simplification, e.g.,
\[ P(\text{cavity} | \text{toothache}, \text{WearsWin}) = P(\text{cavity} | \text{toothache}) = 0.8 \]

This kind of inference, sanctioned by domain knowledge, is crucial

Inference by enumeration

Start with the joint distribution:

<table>
<thead>
<tr>
<th>toothache</th>
<th>¬ toothache</th>
</tr>
</thead>
<tbody>
<tr>
<td>catch</td>
<td>¬ catch</td>
</tr>
<tr>
<td>.108</td>
<td>.012</td>
</tr>
<tr>
<td>.016</td>
<td>.064</td>
</tr>
</tbody>
</table>

For any proposition \( \phi \), sum the atomic events where it is true:
\[ P(\phi) = \sum_{\omega \in \Omega} P(\omega) \]

Product rule gives an alternative formulation:
\[ P(a \land b) = P(a | b)P(b) = P(b | a)P(a) \]

A general version holds for whole distributions, e.g.,
\[ P(\text{Weather}, \text{Cavity}) = P(\text{Weather} | \text{Cavity})P(\text{Cavity}) \]

(Notation for conditional distributions:
\[ P(\text{Cavity} | \text{Toothache}) = 2\text{-element vector of 2\text{-element vectors}} \]

Chapter 13 18

Chain rule is derived by successive application of product rule:
\[ P(X_1, \ldots, X_n) = P(X_1, \ldots, X_{n-1})P(X_n | X_1, \ldots, X_{n-1}) = \ldots = \prod_{i=1}^nP(X_i | X_1, \ldots, X_{i-1}) \]

Chapter 13 19

Inference by enumeration

Start with the joint distribution:

<table>
<thead>
<tr>
<th>toothache</th>
<th>¬ toothache</th>
</tr>
</thead>
<tbody>
<tr>
<td>catch</td>
<td>¬ catch</td>
</tr>
<tr>
<td>.108</td>
<td>.012</td>
</tr>
<tr>
<td>.016</td>
<td>.064</td>
</tr>
</tbody>
</table>

For any proposition \( \phi \), sum the atomic events where it is true:
\[ P(\phi) = \sum_{\omega \in \Omega} P(\omega) \]

Chapter 13 20

P(toothache) = 0.108 + 0.012 + 0.016 + 0.064 = 0.2
Start with the joint distribution:

<table>
<thead>
<tr>
<th></th>
<th>toothache</th>
<th>~toothache</th>
</tr>
</thead>
<tbody>
<tr>
<td>catch</td>
<td>.108</td>
<td>.012</td>
</tr>
<tr>
<td>~catch</td>
<td>.072</td>
<td>.008</td>
</tr>
<tr>
<td>cavity</td>
<td>.016</td>
<td>.064</td>
</tr>
<tr>
<td>~cavity</td>
<td>.144</td>
<td>.576</td>
</tr>
</tbody>
</table>

For any proposition $\phi$, sum the atomic events where it is true:

$$P(\phi) = \sum_{\omega \models \phi} P(\omega)$$

$$P(\text{cavity} \land \text{toothache}) = 0.108 + 0.012 + 0.072 + 0.008 + 0.016 + 0.064 = 0.28$$

Can also compute conditional probabilities:

$$P(\neg \text{toothache} | \text{cavity}) = \frac{P(\neg \text{toothache} \land \text{cavity})}{P(\text{cavity})} = \frac{0.016}{0.108 + 0.012 + 0.072 + 0.008 + 0.016 + 0.064} = 0.4$$

Denominator can be viewed as a normalization constant $\alpha$

$$P(\text{Cavity | toothache}) = \alpha \frac{P(\text{Cavity, toothache})}{\sum_{\omega} P(\omega)}$$

$$\alpha \left[ P(\text{Cavity, toothache, catch}) + P(\text{Cavity, toothache, ~catch}) \right]$$

$$\alpha \left[ (0.108, 0.016) + (0.012, 0.004) \right]$$

$$\alpha (0.12, 0.08) = (0.6, 0.4)$$

General idea: compute distribution on query variable by fixing evidence variables and summing over hidden variables

---

Inference by enumeration, contd.

Let $X$ be all the variables. Typically, we want the posterior joint distribution of the query variables $Y$ given specific values $e$ for the evidence variables $E$

Let the hidden variables be $H = X - Y - E$

Then the required summation of joint entries is done by summing out the hidden variables:

$$P(Y | E = e) = \alpha \sum_{h \in H} P(Y, E = e, H = h)$$

The terms in the summation are joint entries because $Y, E$, and $H$ together exhaust the set of random variables

Obvious problems:

1. Worst-case time complexity $O(d^n)$ where $d$ is the largest arity
2. Space complexity $O(d^n)$ to store the joint distribution
3. How to find the numbers for $O(d^n)$ entries??

---

Independence

$A$ and $B$ are independent iff

$$P(A \land B) = P(A) \cdot P(B)$$

$$P(A, B) = P(A) \cdot P(B)$$

32 entries reduced to 12, for $n$ independent biased coins, $2^n \rightarrow n$

Absolute independence powerful but rare

Dentistry is a large field with hundreds of variables, none of which are independent. What to do?

---

Conditional independence

$P(\text{Toothache, Cavity, Catch})$ has $2^3 - 1 = 7$ independent entries

If I have a cavity, the probability that the probe catches in it doesn’t depend on whether I have a toothache:

1. $P(\text{catch} | \text{toothache, cavity}) = P(\text{catch} | \text{cavity})$

The same independence holds if I haven’t got a cavity:

2. $P(\text{catch} | \text{toothache, ~cavity}) = P(\text{catch} | \text{~cavity})$

$\text{Catch}$ is conditionally independent of $\text{Toothache}$ given $\text{Cavity}$:

$$P(\text{Catch} | \text{Toothache, Cavity}) = P(\text{Catch} | \text{Cavity})$$

Equivalent statements:

$$P(\text{Toothache} | \text{Catch, Cavity}) = P(\text{Toothache} | \text{Cavity})$$

$$P(\text{Toothache} | \text{Catch, Cavity}) = P(\text{Toothache} | \text{Cavity})P(\text{Catch} | \text{Cavity})$$
Conditional independence contd.

Write out full joint distribution using chain rule:
\[ P(\text{Toothache}, \text{Catch}, \text{Cavity}) = P(\text{Toothache}|\text{Catch}, \text{Cavity})P(\text{Catch}, \text{Cavity}) \]
\[ = P(\text{Toothache}|\text{Catch}, \text{Cavity})P(\text{Catch}|\text{Cavity})P(\text{Cavity}) \]
\[ = P(\text{Toothache}|\text{Cavity})P(\text{Catch}|\text{Cavity})P(\text{Cavity}) \]

I.e., \(2 + 2 + 1 = 5\) independent numbers (equations 1 and 2 remove 2)

In most cases, the use of conditional independence reduces the size of the representation of the joint distribution from exponential in \(n\) to linear in \(n\).

Conditional independence is our most basic and robust form of knowledge about uncertain environments.

Bayes’ Rule

Product rule \(P(a \wedge b) = P(a|b)P(b) = P(b|a)P(a)\)

\[ \Rightarrow \text{ Bayes’ rule } P(a|b) = \frac{P(b|a)P(a)}{P(b)} \]

or in distribution form

\[ P(Y|X) = \frac{P(X|Y)P(Y)}{P(X)} = \alpha P(X|Y)P(Y) \]

Useful for assessing diagnostic probability from causal probability:

\[ P(\text{Cause}|\text{Effect}) = \frac{P(\text{Effect}|\text{Cause})P(\text{Cause})}{P(\text{Effect})} \]

E.g., let \(M\) be meningitis, \(S\) be stiff neck:

\[ P(m|s) = \frac{P(s|m)P(m)}{P(s)} = \frac{0.8 \times 0.0001}{0.1} = 0.0008 \]

Note: posterior probability of meningitis still very small!

Bayes’ Rule and conditional independence

\[ P(\text{Cavity}|\text{toothache} \wedge \text{catch}) \]
\[ = \alpha P(\text{toothache} \wedge \text{catch}|\text{Cavity})P(\text{Cavity}) \]
\[ = \alpha P(\text{toothache}|\text{Cavity})P(\text{catch}|\text{Cavity})P(\text{Cavity}) \]

This is an example of a naive Bayes model:

\[ P(\text{Cause}, \text{Effect}_1, \ldots, \text{Effect}_n) = P(\text{Cause}) \prod_{j} P(\text{Effect}_j|\text{Cause}) \]

Total number of parameters is linear in \(n\)

Wumpus World

\[ P_{ij} = \text{true } \text{ iff } [i, j] \text{ contains a pit} \]
\[ B_{ij} = \text{true } \text{ iff } [i, j] \text{ is breezy} \]

Include only \(B_{11}, B_{12}, B_{21}\) in the probability model

Specifying the probability model

The full joint distribution is \(P(P_{1,1}, \ldots, P_{4,4}, B_{1,1}, B_{1,2}, B_{2,1})\)

Apply product rule:

\[ P(B_{1,1}, B_{1,2}, B_{2,1} | P_{1,1}, \ldots, P_{4,4})P(P_{1,1}, \ldots, P_{4,4}) \]

(Do it this way to get \(P(\text{Effect}|\text{Cause})\))

First term: if pits are adjacent to breezes, 0 otherwise
Second term: pits are placed randomly, probability 0.2 per square:

\[ P(P_{1,1}, \ldots, P_{4,4}) = \prod_{i,j=1}^{4} P(P_{i,j}) = 0.2^n \times 0.8^{16-n} \]

for \(n\) pits.

Observations and query

We know the following facts:

\(b = \neg p_{1,1} \wedge \neg b_{1,2} \wedge b_{2,1}\)
\(known = \neg p_{2,1} \wedge \neg p_{1,2} \wedge \neg p_{2,1}\)

Query is \(P(P_{1,3}|\text{known}, b)\)

Define \(Unknown = P_{1,3}\) other than \(P_{1,3}\) and \(Known\)

For inference by enumeration, we have

\[ P(P_{1,3}|\text{known}, b) = 0.5 \prod_{\text{unknown}} p(P_{1,3}, \text{unknown}, \text{known}, b) \]

Grows exponentially with number of squares!
Using conditional independence

Basic insight: observations are conditionally independent of other hidden squares given neighbouring hidden squares

Define \( \text{Unknown} = \text{Fringe} \cup \text{Other} \)

\[
P(b|P_{1,3}; \text{Known, Unknown}) = P(b|P_{1,3}; \text{Known, Fringe})
\]

Manipulate query into a form where we can use this!

Using conditional independence contd.

\[
P(P_{1,3}|\text{known, b}) = \alpha \sum_{\text{unknown}} P(P_{1,3}; \text{unknown, known, b})
\]

\[
= \alpha \sum_{\text{unknown}} P(b|P_{1,3}; \text{known, unknown}) P(P_{1,3}; \text{known, unknown})
\]

\[
= \alpha \sum_{\text{fringe, other}} P(b|\text{known, P}_{1,3}; \text{fringe, other}) P(P_{1,3}; \text{known, fringe, other})
\]

\[
= \sum_{\text{fringe}} P(b|\text{known, P}_{1,3}; \text{fringe}) \sum_{\text{other}} P(P_{1,3}; \text{known, fringe, other})
\]

\[
= \alpha P(\text{known}) P(P_{1,3}; \text{fringe}) \sum_{\text{other}} P(b|\text{known, P}_{1,3}; \text{fringe}) P(\text{fringe}) \sum_{\text{other}} P(\text{other})
\]

\[
= \alpha' P(P_{1,3}; \text{fringe}) \sum_{\text{fringe}} P(b|\text{known, P}_{1,3}; \text{fringe}) P(\text{fringe})
\]

Using conditional independence contd.

\[
P(P_{1,3}|\text{known, b}) = \alpha' (0.2(0.04 + 0.16) + 0.16) \approx (0.31, 0.69)
\]

\[
P(P_{2,3}|\text{known, b}) \approx (0.86, 0.14)
\]

Summary

Probability is a rigorous formalism for uncertain knowledge

Joint probability distribution specifies probability of every atomic event

Queries can be answered by summing over atomic events

For nontrivial domains, we must find a way to reduce the joint size

Independence and conditional independence provide the tools
