

Strategic Games.

N players.

Each player has strategy set. $\{S_1, \dots, S_N\}$.

Vector valued payoff function: $u(s_1, \dots, s_n)$ (e.g., $\in \mathbb{R}^n$).

Example:

2 players

Player 1: { Defect, Cooperate }.

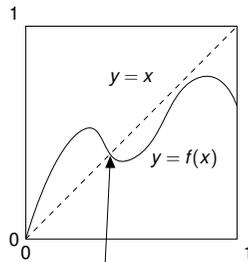

Player 2: { Defect, Cooperate }.

Payoff:

	C	D
C	(3,3)	(0,5)
D	(5,0)	(1,1)

Brouwer Fixed Point Theorem.

Theorem: Every continuous from from a closed compact convex (c.c.c.) set to itself has a fixed point.

Fixed point!

What is the closed convex set here?

The unit square? Or the unit interval?

Famous because?

	C	D
C	(3,3)	(0,5)
D	(5,0)	(1,1)

What is the best thing for the players to do?

Both cooperate. Payoff (3,3).

If player 1 wants to do better, what does she do?

Defects! Payoff (5,0)

What does player 2 do now?

Defects! Payoff (1,1).

Stable now!

Nash Equilibrium:

neither player has incentive to change strategy.

Brouwer implies Nash.

The set of mixed strategies x is closed convex set.

That is, $x = (x_1, \dots, x_n)$ where $\sum x_i = 1$.

$\alpha x' + (1 - \alpha)x''$ is a mixed strategy.

Define $\phi(x_1, \dots, x_n) = (z_1, \dots, z_n)$

where $z_i = \arg \max_{z'_i} [u_i(x_{-i}, z'_i) - \|z_i - x_i\|_2^2]$.

Unique minimum as quadratic.

z_i is continuous in x .

Mixed strategy utilities is polynomial of entries of x with coefficients being payoffs in game matrix.

$\phi(\cdot)$ is continuous on the closed convex set.

Brouwer: Has a fixed point: $\phi(\hat{z}) = \hat{z}$.

Proving Nash.

n players.

Player i has strategy set $\{1, \dots, m_i\}$.

Payoff function for player i : $u_i(s_1, \dots, s_n)$ (e.g., $\in \mathbb{R}^n$).

Mixed strategy for player i : x_i is vector over strategies.

Nash Equilibrium: $x = (x_1, \dots, x_n)$ where

$$\forall i \forall x'_i, u_i(x_{-i}, x'_i) \leq u_i(x).$$

What is x ? A vector of vectors: vector i is length m_i .

What is x_{-i} ? x with x_i replaced by z .

What does say? No new strategy for player i that is better!

Theorem: There is a Nash Equilibrium.

Fixed Point is Nash.

$\phi(x_1, \dots, x_n) = (z_1, \dots, z_n)$ where

$$z_i = \arg \max_{z'_i} [u_i(x_{-i}, z'_i) + \|z_i - x_i\|_2^2].$$

Fixed point: $\phi(\hat{z}) = \hat{z}$

If \hat{z} not Nash, there is i, y_i where

$$u_i(\hat{z}_{-i}, y_i) > u_i(\hat{z}) + \delta.$$

Consider $\hat{y}_i = \hat{z}_i + \alpha(y_i - \hat{z}_i)$.

$u_i(\hat{z}_{-i}, \hat{y}_i) + \|\hat{z}_i - y_i\|^2$?

$$\begin{aligned} u_i(\hat{z}) + \alpha(u_i(\hat{z}) + \delta - u_i(\hat{z})) - \alpha^2 \|\hat{z}_i - y_i\|^2 \\ = u_i(\hat{z}) + \alpha\delta - \alpha^2 \|y_i - \hat{z}_i\|^2 > u_i(\hat{z}). \end{aligned}$$

The last inequality true when $\alpha < \frac{\delta}{\|y_i - \hat{z}_i\|^2}$.

Thus, \hat{z} not a fixed point!

Thus, fixed point is Nash. □

Sperner's Lemma

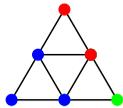

For any $n+1$ -dimensional simplex which is subdivided into smaller simplices.

All vertices are colored $\{1, \dots, n+1\}$.

The coloring is proper if the extremal vertices are differently colored.

Each face only contains the colors of the incident corners.

Lemma: There exist a simplex that has all the colors.

Oops.

Where is multicolored?

Where is multicolored? And now?

By induction!

Proof of Sperner's.

One dimension: Subdivision of $[0, 1]$.

Endpoints colored differently.

Odd number of multicolored edges.

Two dimensions.

Consider $(1, 2)$ edges.

Separates two regions.

Dual edge connects regions with 1 on right.

Exterior region has excess out-degree:

one more $(1, 2)$ than $(2, 1)$.

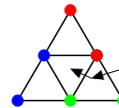

There exist a region with excess in-degree.

$(1, 2, 1)$ triangle has in-degree=out-degree.

$(2, 1, 2)$ triangle has in-degree=out-degree.

Must be $(1, 2, 3)$ triangle.

Must be odd number!

$n+1$ -dimensional Sperner.

R : counts "rainbow" cells; has all $n+1$ colors.

Q : counts "almost rainbow" cells; has $\{1, \dots, n\}$.

Note: exactly one color in $\{1, \dots, n\}$ used twice.

Rainbow face: $n-1$ -dimensional, vertices colored with $\{1, \dots, n\}$.

X : number of boundary rainbow faces.

Y : number of internal rainbow faces.

Number of Face-Rainbow Cell Adjacencies: $R + 2Q = X + 2Y$

Rainbow faces on one face of big simplex.

Induction \implies Odd number of rainbow faces.

$\rightarrow X$ is odd $\rightarrow X + 2Y$ is odd $R + 2Q$ is odd.

R is odd. □

Sperner to Brouwer

Consider simplex: S .

Closed compact sets can be mapped to this.

Let $f(x) : S \rightarrow S$.

Infinite sequence of subdivisions: $\mathcal{S}_1, \mathcal{S}_2, \dots$

\mathcal{S}_j is subdivision of \mathcal{S}_{j-1} . Size of cell $\rightarrow 0$ as $j \rightarrow \infty$.

A coloring of \mathcal{S}_j . Recall $\sum_i x_i = 1$ in simplex.

Big simplex vertices $e_j = (0, 0, \dots, 1, \dots, 0)$ get j .

For a vertex at x .

Assign smallest i with $f(x)_i < x_i$.

Exists? Yes. $\sum_i f(x)_i = \sum_i x_i$.

Valid? Simplex face is at $x_j = 0$ for opposite j .

Thus $f(x)_j$ cannot be smaller and is not colored j .

Rainbow cell, in \mathcal{S}_j with vertices $x^{j,1}, \dots, x^{j,n+1}$.

Rainbow Cells to Brouwer.

Rainbow cell, in \mathcal{S}_j with vertices $x^{j,1}, \dots, x^{j,n+1}$.

Each set of points x_j^i is an infinite set in S .

\rightarrow convergent subsequence \rightarrow has limit point.

\rightarrow All have same limit point as they get closer together.

x^* is limit point.

$f(x)$ has no fixed point $\implies f(x)_i \geq x_i$ for some i . ($\sum_i x_i = 1$).

But $f(x^{j,i})_i < x^{j,i}$ for all j and

$\lim_{j \rightarrow \infty} x^{j,i} = x^*$.

Thus, $(f(x^*))_i \leq x_i^*$ by continuity. Contradiction. □

Computing Nash Equilibrium.

PPAD - "Polynomial Parity Argument on Directed Graphs."

"Graph with an unbalanced node (indegree \neq outdegree) must have another."

Exponentially large graph with vertex set $\{0, 1\}^n$.

Circuit given name of graph finds previous, $P(v)$, and next, $N(v)$.

Sperner: local information gives neighbor.

END OF THE LINE. Given circuits P and N as above, if O^n is unbalanced node in the graph, find another unbalanced node.

PPAD is search problems poly-time reducible to END OF LINE.

NASH \rightarrow BROUWER \rightarrow SPERNER \rightarrow END OF LINE \in PPAD.

Other classes.

PPA: "If an undirected graph has a node of odd degree, it must have another."

PLS: "Every directed acyclic graph must have a sink."

PPP: "If a function maps n elements to $n - 1$ elements, it must have a collision."

All exist: not *NP*!!! Answer is yes. How to find quickly?

Reduction:

END OF LINE \rightarrow Piecewise Linear Brouwer \rightarrow 3D-Sperner \rightarrow Nash.

Uh oh. Nash is PPAD-complete.

Who invented? PapaD and PPAD. Perfect together!
